TWISTED RELATIVE TRACE FORMULAE
WITH A VIEW TOWARDS UNITARY GROUPS

JAYCE R. GETZ AND ERIC WAMBACH

Abstract. We introduce a twisted relative trace formula which simultaneously generalizes the twisted trace formula of Langlands et. al. (in the quadratic case) and the relative trace formula of Jacquet and Lai [JL]. Certain matching statements relating this twisted relative trace formula to a relative trace formula are also proven (including the relevant fundamental lemma in the “biquadratic case”). Using recent work of Jacquet, Lapid and their collaborators [J1] and the Rankin-Selberg integral representation of the Asai $L$-function (obtained by Flicker using the theory of Jacquet, Piatetski-Shapiro, and Shalika [Fl2]), we give the following application: Let $E/F$ be a totally real quadratic extension with $\langle \sigma \rangle = \text{Gal}(E/F)$, let $U^\sigma$ be a quasi-split unitary group with respect to a CM extension $M/F$, and let $U := \text{Res}_{E/F}U^\sigma$. Under suitable local hypotheses, we show that a cuspidal cohomological automorphic representation $\pi$ of $U$ whose Asai $L$-function has a pole at the edge of the critical strip is nearly equivalent to a cuspidal cohomological automorphic representation $\pi'$ of $U$ that is $U^\sigma$-distinguished in the sense that there is a form in the space of $\pi'$ admitting a nonzero period over $U^\sigma$. This provides cohomologically nontrivial cycles of middle dimension on unitary Shimura varieties analogous to those on Hilbert modular surfaces studied by Harder, Langlands, and Rapoport [HLR].

1. Introduction

1.1. Distinction. Let $F$ be a number field and let $G$ be a reductive $F$-group with automorphism $\sigma$ over $F$ of order 2. Write $G^\sigma \leq G$ for the reductive subgroup whose points in an
Let $\pi$ be a cuspidal unitary automorphic representation of $G(\mathbb{A}_F)$. For smooth $\phi$ in the $\pi$-isotypic subspace of the cuspidal subspace $L^2_0(G(F) \backslash G(\mathbb{A}_F)) \leq L^2(G(F) \backslash G(\mathbb{A}_F))$, the period integral

$$P_{G^\sigma}(\phi) := \int_{G^\sigma(F) \backslash G^\sigma(\mathbb{A}_F) \cap G(\mathbb{A}_F)} \phi(x) dx$$

(1.1.1)

converges (see [AGR, Proposition 1, §2]). Here $1^1G(\mathbb{A}_F) \leq G(\mathbb{A}_F)$ is the Harish-Chandra subgroup (see §2.3) and $dx$ is induced by a choice of Haar measure on $G^\sigma(\mathbb{A}_F) \cap G(\mathbb{A}_F)$. If $P_{G^\sigma}(\phi) \neq 0$ for some smooth $\phi$ in the $\pi$-isotypic subspace of $L^2_0(G(F) \backslash G(\mathbb{A}_F))$, we say that $\pi$ is $G^\sigma$-distinguished, or simply distinguished.

Harder, Langlands, and Rapoport introduced the notion of distinction as a tool for producing cohomologically nontrivial cycles on Hilbert modular surfaces. Their work was based on the following observation: If $G(F \otimes_{\mathbb{Q}} \mathbb{R}) \cong G^\sigma(F \otimes_{\mathbb{Q}} \mathbb{R}) \times G^\sigma(F \otimes_{\mathbb{Q}} \mathbb{R})$ and if $\pi$ has nonzero cohomology with coefficients in $\mathbb{C}$ (see Definition 10.2) and is $G^\sigma$-distinguished then there is a differential form $\omega$ on a locally symmetric space attached to $G$ that is $\pi^\infty$-isotypic under the action of certain Hecke correspondences such that $\omega$ has a nonzero period over a sub-symmetric space defined by $G^\sigma$. Harder, Langlands and Rapoport investigated the case where $G = \text{Res}_{\mathbb{Q}(\sqrt{d})/\mathbb{Q}} \text{GL}_2$ for a square-free positive integer $d$ and $\sigma$ is the automorphism of $G$ induced by the nontrivial element of $\text{Gal}(\mathbb{Q}(\sqrt{d})/\mathbb{Q})$. As a consequence of their investigation they proved the Tate conjecture for the “non-CM” part of the cohomology of Hilbert modular surfaces. The key fact that allowed them to link Galois invariant elements in an étale cohomology group to the existence of cycles was a characterization of $\text{GL}_2/\mathbb{Q}$-distinguished cuspidal automorphic representations of $\text{Res}_{\mathbb{Q}(\sqrt{d})/\mathbb{Q}} \text{GL}_2(\mathbb{A}_\mathbb{Q})$ in terms of a certain invariance property of $\pi$ under $\sigma$.

The characterization of $\text{GL}_2/\mathbb{Q}$-distinguished representations used in [HLR] can be proven using a modification of the Rankin-Selberg method [A]. More generally, let $E/F$ be a quadratic extension of number fields. A variation of Jacquet, Piatetskii-Shapiro and Shahi’s interpretation of the Rankin-Selberg method similarly gives some characterization of those automorphic representations of $\text{Res}_{E/F} \text{GL}_n$ distinguished by $\text{GL}_{n/F}$ in terms of Asai $L$-functions [Fl2]. However, in most situations a characterization of the automorphic representations of $G$ distinguished by $G^\sigma$ in terms of arithmetic properties of the automorphic representation or analytic properties of $L$-functions attached to the automorphic representation is unknown.

To address these situations, Jacquet has introduced relative trace formulae in order to provide a (mostly conjectural) conceptual understanding of distinction in great generality. Though the theory still is far from complete, many interesting results are known, even in higher rank. For example, if $E/F$ is a quadratic extension as above, Jacquet, Lapid, and their
collaborators have provided a characterization of those representations of \( \text{Res}_{E/F} \text{GL}_n(\mathbb{A}_F) \) that are distinguished by a quasi-split unitary group in \( n \)-variables attached to \( E/F \) \([J1]\) \([J2]\).

1.2. A result on unitary groups. Since the locally symmetric spaces attached to \( \text{GL}_n \) are never hermitian for \( n > 2 \), the higher rank results of Jacquet and Lapid mentioned above cannot be directly applied to the study of the Tate conjecture for Shimura varieties as in \([HLR]\). Despite this, in this paper we provide one means of relating distinction of automorphic representations of \( \text{GL}_n \) to distinction of automorphic representations on unitary groups (including those defining hermitian locally symmetric spaces). We now state an application. Let \( E/F \) be a quadratic extension of totally real number fields, let \( \langle \sigma \rangle = \text{Gal}(E/F) \), and let \( M/F \) be a CM extension. Let \( U^\sigma \) be a quasi-split unitary group in \( n \) variables attached to the extension \( M/F \) and let \( U := \text{Res}_{E/F} U^\sigma \). We have the following result:

**Theorem 1.1.** Let \( \pi \) be a cuspidal automorphic representation of \( U^\sigma(\mathbb{A}_E) = U(\mathbb{A}_F) \). Suppose that \( \pi \) satisfies the following assumptions:

1. There is a finite-dimensional representation \( V \) of \( U_{F,\infty} \) such that \( \pi \) has nonzero cohomology with coefficients in \( V \).
2. There is a finite place \( v_1 \) of \( F \) totally split in \( ME/F \) such that \( \pi_{v_1} \) is supercuspidal.
3. There is a finite place \( v_2 \neq v_1 \) of \( F \) totally split in \( ME/F \) such that \( \pi_{v_2} \) is in the discrete series.
4. For all places \( v \) of \( F \) such that \( ME/F \) is ramified and \( M/F \), \( E/F \) are both nonsplit at \( v \) the weak base change \( \Pi \) of \( \pi \) to \( U(\mathbb{A}_{ME}) \cong \text{GL}_n(\mathbb{A}_{ME}) \) has the property that \( \Pi_v \) is relatively \( \tau \)-regular.

The representation \( \pi \) admits a weak base change \( \Pi \) to \( \text{GL}_n(\mathbb{A}_{ME}) \). If the partial Asai \( L \)-function \( L^S(s, \Pi; r) \) has a pole at \( s = 1 \) then some cuspidal automorphic representation \( \pi' \) of \( U(\mathbb{A}_F) \) nearly equivalent to \( \pi \) is \( U^\sigma \)-distinguished. Moreover, we can take \( \pi' \) to have nonzero cohomology with coefficients in \( V \).

Here we say two automorphic representations are nearly equivalent if their local factors are isomorphic at almost all places. Moreover, \( S \) is a finite set of places of \( M \) including all infinite places, all places where \( ME/M \) is ramified, and all places below places of \( ME \) where \( \Pi \) is ramified, and

\[
r : L^{\text{Res}_{ME/M}} \text{GL}_n \longrightarrow \text{GL}_{n^2}(\mathbb{C})
\]

is the twisted tensor representation attached to the extension \( ME/M \) (see \([Fl2]\) or \([R, \S6]\) for the definition of this representation). We are also using the fact that \( L^S(s, \Pi; r) \) has a meromorphic continuation to a closed right half plane containing \( s = 1 \) (see \([Fl2]\) and \([FIZ]\)).
Theorem 1.1 is proved as Corollary 10.4 below. For the definition of a relatively $\tau$-regular representation, see §6 below. For other unexplained notation and terminology, see §10. We indicate the role of some of the assumptions in the theorem:

Remarks.

(1) The assumption that $\pi$ is cohomological allows us to use the proof of [HL, Theorem 3.1.4] to conclude that the weak base change $\Pi$ exists.

(2) The assumptions at the places $v_1$ and $v_2$ are made for two reasons. First, they allow us to apply known results on base change liftings from [HL]. Second, they allow us to use the simple form of the relative trace formula proved in [H]. If a relative version of the Arthur-Selberg trace formula were known, together with a theory of relative endoscopy, then it would probably be possible to remove the restrictions on $v_1$ and $v_2$.

(3) Assumption (4) allows us to use test functions supported on the relatively $\tau$-regular semisimple set at places where we have not proven satisfactory matching statements for arbitrary functions. The definition of a relatively $\tau$-regular admissible representation is given in §6 below.

(4) The assumption that $U^\sigma$ is quasi-split is relaxed somewhat in Corollary 10.4 below.

Given all of these simplifying assumptions, one might be surprised that this paper is still rather long. As an explanation, we point out that to prove our theorem we have to provide, from scratch, analogues of many standard constructions in the theory of the usual trace formula (for example, we need analogues of many of the results of [K1], [K3], [K4], [K5]). Unfortunately, this takes some space. We have tried to streamline the presentation by not working in the greatest possible generality.

1.3. Outline of a proof. Let $\pi$ be a cuspidal automorphic representation of $U(\mathbb{A}_F)$ satisfying the hypotheses of Theorem 1.1 and admitting a weak base change $\Pi$ to $\text{Res}_{M/F}\text{GL}_n(\mathbb{A}_F)$ (see §10.1 for our conventions regarding weak base change). Let $\tau$ be the automorphism of $G := \text{Res}_{M/F}\text{GL}_n$ fixing $U$, and let $\theta = \sigma \circ \tau$. We prove Theorem 1.1 in two steps. First, we prove that if $\Pi$ is distinguished by $\text{Res}_{M/F}\text{GL}_n$ and the quasi-split unitary group $G^\theta$ attached to $EM/(EM)^{(\theta)}$ then some automorphic representation $\pi'$ nearly equivalent to $\pi$ is $U^\sigma$ distinguished. We prove this by exhibiting identities of the form

$$\sum_{\pi} \sum_{\phi \in B(\pi)} P_{U^\sigma}(\pi(\Phi^1)\phi)\overline{P_{U^\sigma}(\phi)} = 2 \sum_{\Pi} \sum_{\phi_0 \in B(\Pi)} P_{G^\sigma}(\Pi(f^1)\phi_0)\overline{P_{G^\sigma}(\phi_0)}$$

for a sufficiently large set of functions $f \in C^\infty_c(G(\mathbb{A}_F))$ and $\Phi \in C^\infty_c(U(\mathbb{A}_F))$ that match in the sense of Definition 4.1. Here the sum on the left is over cuspidal automorphic representations of $U(\mathbb{A}_F)$, the sum on the right is over cuspidal automorphic representations of $G(\mathbb{A}_F)$, and $B(\pi)$ is an orthonormal basis of the $\pi$-isotypic subspace of $L^2(U(F)\backslash U(\mathbb{A}_F))$ consisting of smooth vectors; $B(\Pi)$ is defined similarly. We refer the reader to Proposition 9.2 for more details.
Second, the fact that $\Pi$ is a base change implies that $\Pi^\tau \cong \Pi$. By work of Flicker and his collaborators, our assumption on the pole of the Asai $L$-function implies that $\Pi$ is distinguished by $\text{Res}_{M/F} \text{GL}_n$ and moreover that $\Pi^\tau \cong \Pi^\rho$. This implies that $\Pi^\sigma \cong \Pi$, and hence by work of Jacquet, Lapid, and their collaborators this in turn implies that $\Pi$ is distinguished by $G^\theta$. This second step is contained in §10 and we will say no more about it in the introduction.

The proof of the first step is the heart of this paper and is based on a particular case of a general principle which we now explain. Let $H$ be a connected reductive group, let $\langle \tau \rangle = \text{Gal}(M/F)$, and let $G := \text{Res}_{M/F} H$.

Let $\sigma$ be an automorphism of $H$ of order 2 and let $H^\sigma \leq H$ and $G^\sigma \leq G$ be the subgroups fixed by $\sigma$. Let $\theta = \sigma \circ \tau$, viewed as an automorphism of $G$, and let $G^\theta \leq G$ be the subgroup fixed by $\theta$. Let $\pi$ be a cuspidal automorphic representation of $H(A_F)$. Assume that $\pi$ admits a weak base change $\Pi$ to $G(A_F)$. In favorable circumstances the machinery developed in this paper together with suitable fundamental lemmas should imply that if $\Pi$ is $G^\sigma$-distinguished and $G^\theta$-distinguished then a cuspidal automorphic representation $\pi'$ nearly equivalent to $\pi$ is $H^\sigma$-distinguished.

We mention two large obstacles to turning the general principle

$$\Pi \text{ distinguished by } G^\sigma \text{ and } G^\theta \Rightarrow \exists \ H^\sigma \text{-distinguished } \pi' \ \text{nearly equivalent to } \pi$$

into a theorem in any given case. First is the current lack of a relative analogue of the Arthur-Selberg trace formula or a topological relative trace formula. Second is the current lack of a theory of relative endoscopy and the fundamental lemmas that should come along with the theory. If we had the tools of a relative Arthur-Selberg trace formula and the theory of relative endoscopy in hand, one could probably remove the annoying local restrictions in Theorem 1.1 and prove much more general versions of the principle indicated above. However, we caution that if one considers involutions $\sigma$ that are not Galois involutions as we are primarily concerned with in this paper, there seem to be new phenomena lurking that we cannot explain here. These new phenomena may make the principle false as it is stated, though we believe something close to it is true.

We end this outline with some speculation regarding the undefined term “relative endoscopy.” The theory of (twisted) endoscopy, when complete, should yield an understanding of automorphic representations of classical groups in terms of those on general linear groups via a twisted trace formula (see [Ar2, §30], for example). We conjecture that a similar theory will relate distinguished representations on a classical group to representations on $\text{GL}_n$ that are distinguished with respect to two subgroups. We believe that Theorem 1.1 provides an interesting implication of these relations in the special case where endoscopy reduces to base change.
Remark. We note that our approach to the relative trace formula is modeled on that exposed in [JL] and the introduction to [JLR]. More precisely, let $E/F$ be a quadratic extension, suppose $H^o = \text{GL}_2$, $H = \text{Res}_{E/F} \text{GL}_2$, and let $\sigma$ be induced by the nontrivial automorphism $\sigma$ of $\text{Gal}(E/F)$. Then the relatively elliptic part of the trace formula developed in [JL] is roughly the “$\tau = 1$” case of our theory. If we instead let $E = F \oplus F/F$ be the “split” quadratic extension and again let $\sigma$ be the automorphism of $H$ induced by the nontrivial $F$-automorphism of $E/F$, then our trace formula comparing distinction on $G := \text{Res}_{M/F} H$ to distinction on $H$ is roughly equivalent to the “elliptic part” of the trace formula comparison used to establish quadratic base change in [L1] (though, of course, Langlands treats general cyclic extensions). This justifies our claim in the abstract that our formulae simultaneously generalize the relative trace formula and the twisted trace formula (in the quadratic case). See Proposition 9.2 for a precise statement regarding trace formula comparisons.

We now give a synopsis of the various sections. We fix some notation in the next section. In §3.1, following [JL] we develop a notion of relative classes and relative $\tau$-classes generalizing conjugacy classes and twisted conjugacy classes, respectively. A norm map is also defined and studied, and in §3.3 we prove that it has the properties one would expect, at least in the “biquadratic unitary” case (see §3.1).

Section 4 studies the corresponding notion of matching of stable local relative orbital integrals. We also prove the fundamental lemma for unit elements in the “biquadratic case” and the fundamental lemma for Hecke functions when various objects split (e.g. $M/F$). In §5 we prove that one can find some function in $C_c^\infty(H(F_v))$ matching a given function in $C_c^\infty(G(F_v))$ for nonarchimedian $v$. We define the notion of a relatively $\tau$-regular admissible representation in §6; we require this notion due to our incomplete knowledge of matching functions.

Section 7 concerns globalization of stable relative orbital integrals. Here we follow Labesse’s formulation [La1] of the work of Kottwitz and Shelstad (following Langlands, see [KS], [L2]) on the usual trace formula. In §8 we discuss the geometric expansion of the stable twisted relative trace formula. In §9 we use the main theorem of [H] together with all of the previous work to give a spectral expansion of the twisted relative trace formula on $G$ and the relative trace formula on $H$, at least in the case relevant for the proof of Theorem 1.1. As noted above, §10 contains the final argument proving Theorem 1.1.

2. Selected notation and conventions

2.1. Algebraic groups. Let $G$ be an algebraic group over a field $F$. We write $Z_G$ for the center of $G$ and $G^o$ for the identity component of $G$ in the Zariski topology. If $\gamma \in G(F)$ and $G' \leq G$ is a subgroup we write $C_{\gamma,G'}$ for the centralizer in $G'$ of $\gamma$. If the element $\gamma$ is semisimple then we say it is elliptic if $C_{\gamma,G}/Z_G$ is anisotropic. If $\tau$ is an automorphism of
$G$ and $\gamma \in G(R)$ for some commutative $F$-algebra $R$ we write

$$\gamma^{-\tau} := (\gamma^{-1})^\tau.$$  

We write $C_{\gamma, G}^\tau$ for the $\tau$-centralizer of $\gamma$ in $G$; it is the reductive $F$-group whose points in an $F$-algebra $R$ are given by

$$C_{\gamma, G}^\tau(R) := \{ g \in G(R) : g^{-1}\gamma g^\tau = \gamma \}.$$  

A torus $T \leq G$ is said to be $\tau$-split if for any commutative $F$-algebra $R$ we have $g^\tau = g^{-1}$ for all $g \in T(R)$. If $\theta$ is another automorphism of $G$, we say that $T$ is $(\tau, \theta)$-split if it is both $\tau$ and $\theta$-split.

### 2.2. Adèles.

The adèles of a number field $F$ are denoted by $\mathbb{A}_F$. For a set of places $S$ of $F$ we write $\mathbb{A}_{F,S} := \mathbb{A}_F \cap \prod_{v \in S} F_v$ and $\mathbb{A}_F^S := \mathbb{A}_F \cap \prod_{v \in S} F_v$. If $S$ is finite we often write $F_S := \mathbb{A}_{F,S}$. The set of infinite places of $F$ will be denoted by $\infty$. Thus $\mathbb{A}_{\mathbb{Q}, \infty} = \mathbb{R}$ and $\mathbb{A}_\infty^\mathbb{Q} := \prod_{p \in \mathbb{Z}_{>0}} \mathbb{Q}_p$. For an affine $F$-variety $G$ and a subset $W \leq G(A_{F})$ the notation $W_S$ (resp. $W^S$) will denote the projection of $W$ to $G(\mathbb{A}_{F,S})$ (resp. $G(\mathbb{A}_F^S)$). If $W$ is replaced by an element of $G(\mathbb{A}_F)$, or if $G$ is an algebraic group and $W$ is replaced by a character of $G(\mathbb{A}_F)$ or a Haar measure on $G(\mathbb{A}_F)$, the same notation will be in force; e.g. if $\gamma \in G(\mathbb{A}_F)$ then $\gamma_v$ is the projection of $\gamma$ to $G(F_v)$.

### 2.3. Harish-Chandra subgroups.

Let $G$ be a connected reductive group over a number field $F$. We write $A_G \leq Z_G(F \otimes_{\mathbb{Q}} \mathbb{R})$ for the connected component of the real points of the largest $\mathbb{Q}$-split torus in the center of $\text{Res}_{F/\mathbb{Q}} G$. Here when we say “connected component” we mean in the real topology. Write $X$ for the group of $\mathbb{Q}$-rational characters of $G$. There is a morphism

$$HC_G : G(\mathbb{A}_F) \longrightarrow \text{Hom}(X, \mathbb{R})$$

defined by

$$\langle HC_G(x), \chi \rangle = |\log(x^\chi)|$$

for $x \in G(\mathbb{A}_F)$ and $\chi \in X$. We write

$$1^G(\mathbb{A}_F) := \ker(HC_G)$$

and refer to it as the Harish-Chandra subgroup of $G(\mathbb{A}_F)$. Note that $G(F) \leq 1^G(\mathbb{A}_F)$ and $G(\mathbb{A}_F)$ is the direct product of $A_G$ and $1^G(\mathbb{A}_F)$. 

3. Twisted relative classes and norm maps

In this section we recall the notion of relative classes in algebraic groups with involution and extend this notion to the “τ-twisted” case. In §3.2 we define stable relative classes and a relative version of the usual norm map, which, in the original setting of the trace formula, relates τ-conjugacy classes and conjugacy classes. In §3.3 we use work of Borovoi to show that the norm map has particularly nice properties in the “biquadratic unitary case.”

3.1. Twisted relative classes. Let $F$ be a number field and let $M/F$ be either a quadratic or a trivial extension. Let $τ$ be the generator of $\text{Gal}(M/F)$. Fix, once and for all, an algebraic closure $\overline{M}$ of $M$. We usually regard $\overline{M}$ as an algebraic closure of $F$ as well, and denote it by $\overline{F}$. For all places $v$ of $F$, choose once and for all an algebraic closure $\overline{F}_v$ of the completion $F_v$ of $F$ and a compatible system of embeddings $\overline{F} \hookrightarrow \overline{F}_v$.

Let $H$ be a reductive $F$-group with (semisimple) automorphism $σ$ of order two (defined over $F$). We let $H^σ$ be the reductive $F$-group whose points in an $F$-algebra $R$ are given by

$$H^σ(R) := \{g \in H(R) : g^σ = g\}.$$

We assume that

- $H^σ$ is connected.

This will always be the case if $H$ is semisimple and simply connected [St1, §8]. Write

$$G := \text{Res}_{M/F} H$$

$$G^σ := \text{Res}_{M/F} H^σ.$$

The automorphism $σ$ of $H$ induces an automorphism of $G$ which we will also denote by $σ$. Set $θ := σ \circ τ$ (where $σ$ and $τ$ are viewed as automorphisms of $G$), and write $G^θ \leq G$ for the subgroup whose points in an $F$-algebra $R$ are given by

$$G^θ(R) := \{g \in G(R) : g = g^θ\}.$$

We note that $θ$, $σ$, and $τ$ all commute.

Remark. Let $E/F$ be a quadratic extension of number fields with $ME/F$ biquadratic. The primary case of interest for us in this paper is the case where $H = \text{Res}_{E/F} H^σ$ and $σ$ is the automorphism of $H$ defined by the generator of $\text{Gal}(E/F)$ (which we will also denote by $σ$). We refer to this case as the biquadratic case.

We have left actions of $H^σ \times H^σ$ on $H$ and $G^σ \times G^θ$ on $G$ given by

$$(H^σ \times H^σ)(R) \times H(R) \rightarrow H(R)$$

(3.1.1)

$$(g_1, g_2, g) \mapsto (g_1 g g^{-1}_2)$$

$$(G^σ \times G^θ)(R) \times G(R) \rightarrow G(R)$$

$$(g_1, g_2, g) \mapsto (g_1 g g^{-1}_2)$$
for $F$-algebras $R$. Our goal in this section is to compare the sets of double cosets $H^\sigma(R) \setminus H(R) / H^\sigma(R)$ and $G^\sigma(R) \setminus G(R) / G^\theta(R)$.

For this purpose, following [Ri, Lemma 2.4] we introduce the subschemes $Q := Q_H \subset H$ and $S := S_G \subset G$. They are defined to be the scheme theoretic images of the morphisms given on points in an $F$-algebra $R$ by

$$B_\sigma : H(R) \longrightarrow H(R)$$

$$g \mapsto gg^{-\sigma}$$

$$B_\theta : G(R) \longrightarrow G(R)$$

$$g \mapsto gg^{-\theta},$$

respectively; they are closed affine $F$-subschemes of $H$ and $G$, respectively (see [HW, §2.1]). Notice that $B_\sigma(g_1gg_2^{-1}) = g_1B_\sigma(g)g_1^{-1}$ and $B_\theta(g_1gg_2^{-1}) = g_1B_\theta(g)g_1^{-\tau}$ for $(g_1, g_2) \in H^\sigma(R)^2$ (resp. $(g_1, g_2) \in G^\sigma \times G^\theta(R)$). There are injections

$$H^\sigma(R) \setminus H(R) / H^\sigma(R) \longrightarrow H^\sigma(R) \setminus Q(R)$$

$$g \mapsto gg^{-\sigma}$$

$$G^\sigma(R) \setminus G(R) / G^\theta(R) \longrightarrow G^\sigma(R) \setminus S(R)$$

$$g \mapsto gg^{-\theta}$$

where $H^\sigma$ acts by conjugation on $Q$ and $G^\sigma$ acts by $\tau$-conjugation on $S$.

For any $F$-algebra $k$ and any $\gamma \in H(k)$ (resp. $\delta \in G(k)$) write $H_\gamma$ (resp. $G_\delta$) for the $k$-group whose points in a commutative $k$-algebra $R$ are given by

$$H_\gamma(R) : = \{(g_1, g_2) \in H^\sigma(R) \times H^\sigma(R) : g_1^{-1}\gamma g_2 = \gamma\}$$

$$G_\delta(R) : = \{(g_1, g_2) \in G^\sigma(R) \times G^\theta(R) : g_1^{-1}\delta g_2 = \delta\}.$$

Write $C_{\gamma,H^\sigma}$ (resp. $C_{\delta,G^\sigma}^\tau$) for the centralizer of $\gamma$ in $H^\sigma$ (resp. $\tau$-centralizer of $\delta$ in $G^\sigma$).

**Lemma 3.1.** There are isomorphisms $H_\gamma \rightarrowtail C_{\gamma^{-\sigma},H^\sigma}$ and $G_\delta \rightarrowtail C_{\delta^{-\theta},G^\sigma}^\tau$ given on a $k$-algebra $R$ by

$$H_\gamma(R) \rightarrowtail C_{\gamma^{-\sigma},H^\sigma}(R)$$

$$(g_1, g_2) \mapsto g_1$$

$$G_\delta(R) \rightarrowtail C_{\delta^{-\theta},G^\sigma}^\tau(R)$$

$$(g_1, g_2) \mapsto g_1.$$

**Proof.** Injectivity is clear. For surjectivity, note that if $g_1^{-1}\gamma^{-\sigma}g_1 = \gamma^{-\sigma}$ for $g_1 \in H^\sigma(R)$ then

$$\gamma^{-1}g_1^{-1}\gamma = \gamma^{-\sigma}g_1^{-1}\gamma^\sigma = (\gamma^{-1}g_1^{-1}\gamma)^\sigma,$$
so \((g_1, (\gamma^{-1}g_1^{-1}\gamma)^{-1}) \in H_\gamma(R)\). Similarly, if \(g_1^{-1}\delta\delta^{-\theta}g_1^{-1}\delta = \delta\delta^{-\theta}\) for \(g_1 \in G^\sigma(R)\), then
\[
\delta^{-1}g_1^{-1}\delta = \delta^{-\theta}g_1^{-1}\delta^{-\theta} = (\delta^{-1}g_1^{-1}\delta)^{\theta} = (\delta^{-1}g_1^{-1}\delta)^{\theta}
\]
so \((g_1, (\delta^{-1}g_1^{-1}\delta)^{-1}) \in G_\delta(R)\). □

**Lemma 3.2.** Let \(k/F\) be a field, let \(\gamma \in H(k)\) and \(\delta \in G(k)\). If \(\gamma\gamma^{-\sigma}\) is semisimple (resp. \(\delta\delta^{-\theta}\) is \(\tau\)-semisimple) then \(C_{\gamma\gamma^{-\sigma},H^\sigma}\) (resp. \(C_{\tau\delta\delta^{-\theta},G^\sigma}\)) is reductive.

**Proof.** See [H, §2]. □

We also often use the following lemma:

**Lemma 3.3.** Let \(k/F\) be a field, let \(\gamma \in H(k)\) and \(\delta \in G(k)\). Assume we are in the biquadratic case and that \((H^\sigma)^{\text{des}}\) is simply connected. If \(\gamma\gamma^{-\sigma}\) is semisimple (resp. \(\delta\delta^{-\theta}\) is \(\tau\)-semisimple) then \(C_{\gamma\gamma^{-\sigma},H^\sigma}\) (resp. \(C_{\tau\delta\delta^{-\theta},G^\sigma}\)) is connected.

**Proof.** Recall that for any semisimple \(x \in H^\sigma(k)\) the group \(C_{x,H^\sigma}\) is connected by a theorem of Steinberg ([St1], [K1, §3]). Upon passing to the algebraic closure, it is easy to see that this fact implies the lemma. □

For an \(F\)-algebra \(R\) write
\[
(3.1.6) \quad \Gamma_r(R) := H^\sigma(R)\backslash H(R)/H^\sigma(R) \\
\Gamma_{\tau\tau}(R) := G^\sigma(R)\backslash G(R)/G^\theta(R).
\]

We refer to the elements of \(\Gamma_r(R)\) (resp. \(\Gamma_{\tau\tau}(R)\)) as relative classes (resp. relative \(\tau\)-classes). If two elements \(\gamma, \gamma' \in H(R)\) (resp. \(\delta, \delta' \in G(R)\)) map to the same class in \(\Gamma_r(R)\) (resp. \(\Gamma_{\tau\tau}(R)\)) we say that they are in the same relative class (resp. relative \(\tau\)-class). In this paper we will loosely refer to any construction or object involving relative \(\tau\)-classes as the twisted case.

The following definitions are adaptations of those appearing in [JL] and [Fl3]:

**Definition 3.4.** Let \(k/F\) be a field. An element \(\gamma \in H(k)\) is **relatively semisimple** (resp. relatively elliptic, relatively regular) if \(\gamma\gamma^{-\sigma}\) is semisimple (resp. elliptic, regular) as an element of \(H(k)\).

**Definition 3.5.** Let \(k/F\) be a field. An element \(\delta \in G(k)\) is **relatively \(\tau\)-semisimple** (resp. relatively \(\tau\)-elliptic, relatively \(\tau\)-regular) if \(\delta\delta^{-\theta}\) is \(\tau\)-semisimple (resp. \(\tau\)-elliptic, \(\tau\)-regular) in the usual sense.

For brevity, we say that \(\delta\) is relatively \(\tau\)-regular semisimple if it is both relatively \(\tau\)-regular and relatively \(\tau\)-semisimple, with similar conventions regarding other combinations of regular, semisimple, and elliptic. It is easy to check that \(\gamma \in H(R)\) is relatively semisimple (resp. elliptic, regular) if and only if every element in \(H^\sigma(R)\gamma H^\sigma(R)\) is relatively semisimple.
(resp. elliptic, regular). A similar statement holds in the twisted case. For a field $k/F$ we denote by
\begin{align}
\Gamma^s_r(k) := & \{ H^\sigma(k) \gamma H^\sigma(k) \in \Gamma_r(k) : \gamma \text{ is relatively semisimple} \} \\
\Gamma^s_{r\tau}(k) := & \{ G^\sigma(k) \delta G^\sigma(k) \in \Gamma_{r\tau}(k) : \delta \text{ is relatively } \tau\text{-semisimple} \}.
\end{align}

Let $Q^{ss} \subset Q$ be the subscheme whose points in an $F$-algebra $R$ are semisimple elements of $H(R)$.

**Lemma 3.6.** Assume that we are in the biquadratic case and $H^\text{der}$ is simply connected. For $k$ either $F$ or $F_v$ for some place $v$ of $F$ the natural morphism (3.1.2) induce a bijection
\[ \Gamma^s_r(k) \leftrightarrow H^\sigma(k) \backslash Q^{ss}(k). \]

**Proof.** We claim that every element of $Q^{ss}(k)$ is of the form $\gamma \gamma^{-\sigma}$ for some $\gamma \in H(k)$. To prove the claim, first let $\alpha \in Q^{ss}(k)$ and consider $C_{\alpha,H}(k)$. Since $\alpha$ is semisimple and $H^\text{der}$ is simply connected, $C_{\alpha,H}$ is a (connected) reductive group ([St1], [K1, §3]). Using the fact that $\alpha = \alpha^{-\sigma}$, it is trivial to check that $C_{\alpha,H}$ is $\sigma$-invariant, and it follows that $C_{\alpha,H} = \text{Res}_{E \otimes F_{k/k}} I$ for some reductive subgroup $I \leq H^\sigma$. Let $T' \leq I$ be a maximal torus and let $T = \text{Res}_{E \otimes F_{k/k}} T'$. Then $\alpha$ is in the centralizer of $T$ in $C_{\alpha,H}$, and it follows that $\alpha \in T(k)$ [B, §IV.11.12].

Denoting by $\langle \sigma \rangle$ the subgroup of the group of automorphisms of $T(k)$ generated by $\sigma$, we have
\[ N_{\langle \sigma \rangle} T(k)/I_{\langle \sigma \rangle} T(k) = \hat{H}^{-1}(\langle \sigma \rangle, T(k)) \cong H^1(\langle \sigma \rangle, T(k)) \cong 1 \]
(see [S1, §VIII.1 and §VIII.4] for notation and the existence of the first isomorphism). Here we have used Shapiro’s lemma for the last isomorphism. By definition of $N_{\langle \sigma \rangle} T(k)/I_{\langle \sigma \rangle} T(k)$, it follows that $\alpha = \gamma \gamma^{-\sigma}$ for some $\gamma \in T(k)$. This completes the proof of our claim. We leave to the reader the straightforward task of deducing the lemma from the claim. \qed

### 3.2. Norms of stable classes: Definitions.

In this subsection we define stable classes and a notion of norm. We assume throughout the subsection that $k$ is either $F$ or $F_v$ for some place $v$ of $F$. In this section and for the remainder of the paper, we will always make the following simplifying assumption:

- For all relatively semisimple $\gamma \in H(\overline{F})$ the group $H_\gamma$ is connected.

By passing to an algebraic closure, it is easy to see that this assumption implies that $G_\delta$ is connected for all relatively $\tau$-semisimple $\delta \in G(\overline{F})$. For a condition sufficient to ensure the assumption above holds, see Lemma 3.3.

**Definition 3.7.** Two relatively semisimple elements $\gamma, \gamma_0 \in H(k)$ are in the same **stable relative class** if and only if $x \gamma \gamma^{-\sigma} x^{-1} = \gamma_0 \gamma_0^{-\sigma}$ for some $x \in H^\sigma(\overline{k})$. 

Similarly, two elements $\delta, \delta_0 \in G(k)$ are in the same **stable relative** $\tau$-class if and only if $y\delta\delta^{-\theta}y^{-\tau} = \delta_0\delta_0^{-\theta}$ for some $y \in G^\sigma(k)$.

For a pair of reductive $k$-groups $I, H$, define
$$D(I, H; k) := \ker \left[ H^1(k, I) \to H^1(k, H) \right].$$

We note that the set of relative classes in the stable relative class of $\gamma_0 \in H(k)$ is in bijection with
$$D(C_{\gamma_0 \gamma_0^{-\sigma}, H^\sigma} ; H^\sigma ; k) \quad \text{(3.2.1)}$$
and the set of relative $\tau$-classes in the stable relative $\tau$-class of $\delta_0 \in G(k)$ is in bijection with
$$D(C_{\delta_0 \delta_0^{-\theta}, G^\sigma} ; G^\sigma ; k). \quad \text{(3.2.2)}$$

In particular, if $k = F_v$ for some place $v$ of $F$, then both of these sets of stable classes are finite (compare [La1, §1.8, §2.3]).

Later, when defining orbital integrals, the following observation will be useful. Suppose that $\gamma, \gamma_0$ are in the same stable relative class; choose $x$ as in Definition 3.7. Then we have an inner twist

$$H_\gamma(\bar{k}) \to C_{\gamma \gamma^{-\sigma}, H^\sigma}(\bar{k}) \to C_{\gamma_0 \gamma_0^{-\sigma}, H^\sigma}(\bar{k}) \to H_{\gamma_0}(\bar{k})$$
$$g \mapsto xgx^{-1} \quad \text{(3.2.3)}$$

where the first and last isomorphism are those of (3.1.5) (compare [K1, Lemma 3.2]). Similarly, if $\delta, \delta_0$ are in the same stable relative $\tau$-class, choose $y$ as in Definition 3.7. Then there is an inner twisting

$$G_\delta(\bar{k}) \to C_{\delta \delta^{-\theta}, G^\sigma}(\bar{k}) \to C_{\delta_0 \delta_0^{-\theta}, G^\sigma}(\bar{k}) \to G_{\delta_0}(\bar{k})$$
$$g \mapsto ygy^{-1}. \quad \text{(3.2.4)}$$

We have the following definition:

**Definition 3.8.** Suppose that $\gamma \in H(k)$ is relatively semisimple. We say that $\gamma$ is a **norm** of $\delta \in G(k)$ if there is an $y \in G^\sigma(\bar{k})$ such that
$$y\delta\delta^{-\theta}(\delta\delta^{-\theta})^{-\tau}y^{-1} = \gamma\gamma^{-\sigma}.$$

The following lemma together with Proposition 3.10 below can be used to show that norms exist in certain cases:

**Lemma 3.9.** Suppose that $\delta \in G(k)$ is relatively $\tau$-semisimple. Let $O(\bar{k}) \subset Q(\bar{k})$ denote the subset of elements that are $G^\sigma(\bar{k})$-conjugate to $\delta\delta^{-\theta}(\delta\delta^{-\theta})^{-\sigma} = \delta\delta^{-\theta}(\delta\delta^{-\theta})^{-\tau}$. Then $O(\bar{k})$ is fixed by $\text{Gal}(\bar{k}/k)$ and is the set of $k$-points of a (nonempty) homogeneous space $O$ for $H_k^\sigma$. Any $\gamma \in H(k)$ such that $\gamma\gamma^{-\sigma} \in O(k)$ is a norm of $\delta$. 

Proof. Let $\tilde{Q} := \text{Res}_{M/F} Q$; it is the scheme theoretic image of the map $G \to G$ defined by

$$G(R) \to G(R)$$

$$g \mapsto gg^{-\sigma}$$

for $F$-algebras $R$. The group scheme $G^\sigma$ acts on $\tilde{Q}$ by conjugation. Note that $\delta\delta^{-\theta}(\delta\delta^{-\theta})^\tau \in \tilde{Q}(k)$. We claim that a $G^\sigma(\overline{k})$-conjugate $\gamma$ of $\delta\delta^{-\theta}(\delta\delta^{-\theta})^\tau$ is contained in $Q(\overline{k})$. Assuming the claim for a moment, it is easy to check that

$$O(\overline{k}) := \{ h^{-1}\gamma h : h \in H^\sigma(\overline{k}) \} = \{ g^{-1}\delta\delta^{-\theta}(\delta\delta^{-\theta})^\tau g : g \in G^\sigma(\overline{k}) \} \cap Q(\overline{k}) .$$

Since the set on the right is fixed by $\text{Gal}(\overline{k}/k)$, the set on the left is as well. It follows that $O(\overline{k})$ is the set of $k$-points of a homogeneous space $O$ for $H^\sigma_k$.

Choose an isomorphism

$$G^\sigma_{\overline{k}} \to H_{\overline{k}} \times H_{\overline{k}}$$

equivariant with respect to $\sigma$ and intertwining $\tau$ with $(x, y) \mapsto (y, x)$. Let $(\delta_1, \delta_2)$ be the image of $\delta\delta^{-\theta}$ under this isomorphism. Then $\delta_2 = \delta_1^{-\sigma}$. Replacing $\delta\delta^{-\theta}$ by $g^{-1}\delta\delta^{-\theta}g^\tau$ for some $g \in G^\sigma(\overline{k})$ does not affect the $G^\sigma(\overline{k})$-conjugacy class of $\delta\delta^{-\theta}(\delta\delta^{-\theta})^\tau$. Translating this statement to $H_{\overline{k}} \times H_{\overline{k}}$ using (3.2.5), we see that to prove the claim it suffices to exhibit $h_1, h_2 \in H^\sigma(\overline{k})$ such that $h_1^{-1}\delta_1 h_2 = h_2^{-1}\delta_2 h_1$. Since $h_2^{-1}\delta_2 h_1 = (h_1^{-1}\delta_1 h_2)^{-\sigma}$, this is equivalent to the statement that $\delta_1$ is in the relative class of an element $t$ satisfying $t^{-\sigma} = t$. Because $\delta\delta^{-\theta}(\delta\delta^{-\theta})^\tau$ is semisimple by assumption, $\delta_1$ is relatively semisimple. Thus $\delta_1$ is in the relative class of an element $t$ of a $\sigma$-split torus by [Ri, Theorem 7.5]. This element satisfies $t = t^{-\sigma}$. \qed

Suppose that $\gamma \in H(k)$ is a norm of $\delta \in G(k)$. We then have an inner twist

$$G^\sigma(\overline{k}) \to G^\sigma_{\overline{\delta\delta^{-\theta}}}(\overline{k}) \to C_{\overline{\delta\delta^{-\theta}}(\delta\delta^{-\theta})^\tau, H^\sigma}(\overline{k}) \to C_{\gamma^{-\sigma}, H^\sigma}(\overline{k}) \to H^\sigma(\overline{k})$$

$$g \mapsto gyy^{-1}$$

for $y$ as in Definition 3.8. Here the first and last isomorphism are those of (3.1.5), and the second is the restriction to $C_{\overline{\delta\delta^{-\theta}}, G^\sigma}$ of the projection of $G^\sigma(\overline{k}) \cong H^\sigma(\overline{k}) \times H^\sigma(\overline{k})$ onto the factor indexed by the identity.

### 3.3. Existence of norms

If we were in the standard trace formula setting, now would be the point where we would use the Kottwitz-Steinberg theorem, which states that a conjugacy class defined over $F$ in a quasi-split reductive group with simply connected derived group contains an element [K1], and therefore (in this setting) norms exist. Unfortunately, no general analogue of this theorem is known in the relative setting. In fact, preliminary investigations suggest that it is not true.
In this subsection we provide a conditional relative analogue of the Kottwitz-Steinberg theorem using work of Borovoi. We say that \( H \) is a unitary group if there is an \( F \)-algebra \( D \) and an involution \( \dagger : D \to D \) of the second kind such that \( H(R) \) is equal to
\[
\{ g \in (D \otimes_F R)^	imes : gg^\dagger = 1 \}
\]
for \( F \)-algebras \( R \). We assume in addition that either \( D \) is simple or the center of \( D \) is \( F \oplus F \) and \( D = D_0 \times D_0 \) for some simple algebra \( D_0 \). Throughout this subsection we always assume that \( H \) is a unitary group and that we are in the biquadratic case. Thus \((H^\sigma)_{\text{der}}\) is simply connected. Moreover since we are in the biquadratic case we have \( \operatorname{Z}_H \leq \operatorname{Z}_{H^\sigma} \), so the \( H^\sigma \)-orbit of any \( \alpha \in \mathbb{Q}(F) \) under conjugation is equal to its orbit under the subgroup \((H^\sigma)_{\text{der}}\). This fact is used in the proof of the following proposition:

**Proposition 3.10.** If \( \delta \in G(F) = \operatorname{Res}_{M/F} H(F) \) is relatively \( \tau \)-regular semisimple, the element \( \delta_{v_0} \) is relatively \( \tau \)-elliptic for some place \( v_0 \), and for all \( v|\infty \) there is a \( \gamma \in H(F_v) \) that is a norm of \( \delta \in G(F_v) \), then there is a \( \gamma \in H(F) \) such that \( \gamma \) is a norm of \( \delta \).

Before proving Proposition 3.10 we will state and prove a converse to it:

**Lemma 3.11.** Let \( k \) be either \( F \) or \( F_v \) for some place \( v \) of \( F \). If \( \gamma \in H(k) \) is relatively semisimple, then it is a norm of some \( \delta \in G(k) \). In fact, \( \gamma \gamma^{-\sigma} = \delta \delta^{-\theta} (\delta \delta^{-\theta})^\tau \) for some \( \delta \in G(k) \).

**Proof.** By the proof of Lemma 3.6, for any relatively semisimple \( \gamma \in H(k) \) we can choose a \( \sigma \)-stable torus \( T \leq H_k \) such that \( \gamma \gamma^{-\sigma} \) is in the image of the map
\[
T(k) \longrightarrow Q(k)
\]
\( g \longmapsto gg^{-\sigma} \).

Let \( \widetilde{T} := \operatorname{Res}_{M \otimes k/k} T \leq G_k \). Then we have two composite maps
\[
\psi_1 : \widetilde{T}(k) \xrightarrow{x \mapsto xx^\theta} T(k) \xrightarrow{y \mapsto yy^{-\sigma}} T \cap Q(k)
\]
\[
\psi_2 : \widetilde{T}(k) \xrightarrow{x \mapsto xx^\theta} \widetilde{T} \cap S(k) \xrightarrow{y \mapsto yy^\tau} T \cap Q(k).
\]
It suffices to show that \( \psi_2 \) is surjective. Since all of the groups in the definition of the \( \psi_i \) are commutative, \( \psi_1 = \psi_2 \), so it suffices to show that \( \psi_1 \) is surjective. The second map in the definition of \( \psi_1 \) is surjective by the argument in the proof of Lemma 3.6. The first map is surjective by [Ro2, Proposition 3.11.1(a)].

We prove Proposition 3.10 using a cohomological obstruction to the existence of points in a homogeneous space developed in [Bo1]. In order to use Borovoi’s results, we must develop a little notation. Set
\[
(3.3.1) \quad \ker^j(F, \cdot) := \ker(H^j(F, \cdot) \to \prod_v H^j(F_v, \cdot))
\]
where the product is over all places of \( v \). Let \( H \) be an \( F \)-group and let \( X \) be a homogeneous space for \( H \). Suppose for simplicity that the stabilizer \( H_\mathfrak{p} \) of a point \( \mathfrak{x} \in X(\mathbb{F}) \) is connected and reductive. The stabilizer \( H_\mathfrak{p} \) is not in general the base change to \( \mathbb{F} \) of an algebraic group over \( F \). However, as explained in [Bo1, §1.7], the maximal toric quotient \( H_\mathfrak{p}/H_\mathfrak{p}^{\text{der}} \) has a canonical \( F \)-form. We denote this \( F \)-form by \( C_{\mathfrak{p},H}^m \). The obstruction \( \text{Ob}(H,X) \) lies in \( \ker^2(F,C_{\mathfrak{p},H}^m) \) [Bo1, §1.5].

We now prove Proposition 3.10:

**Proof.** Let \( \alpha = \delta \delta^{-\theta}(\delta \delta^{-\theta})^\tau \). By Lemma 3.9 the set of elements of \( Q(\mathbb{F}) \) that are \( G^\sigma(\mathbb{F}) \)-conjugate to \( \alpha \) defines a homogeneous space \( O(\alpha) \) for \( H^\sigma \) and hence also for \( (H^\sigma)^{\text{der}} \) since \( Z_{H^\sigma} \leq Z_H \). By [Bo1, Theorem 1.6] it suffices to show that

\[
\text{Ob}((H^\sigma)^{\text{der}}, O(\alpha)) \in \ker^2(F,C_{\alpha,(H^\sigma)^{\text{der}}}^m)
\]

is trivial; to do this we will show that \( (C_{\alpha,(H^\sigma)^{\text{der}}}^m)_{F_\mathfrak{p}} \) is anisotropic and hence \( \ker^2(F,C_{\alpha,(H^\sigma)^{\text{der}}}^m) = 0 \) by [Sa, Lemme 1.9]. One checks via [Bo1, §1.7] that there is a natural injection

\[
C_{\alpha,(H^\sigma)^{\text{der}}}^m \longrightarrow C_{\alpha,H^\sigma}^m
\]

and \( Z_{H^\sigma}C_{\alpha,(H^\sigma)^{\text{der}}}^m = C_{\alpha,H^\sigma}^m \). Hence to prove that the torus \( (C_{\alpha,(H^\sigma)^{\text{der}}}^m)_{F_\mathfrak{p}} \) is anisotropic it suffices to show that the torus \( (C_{\alpha,H^\sigma}/Z_{H^\sigma})_{F_\mathfrak{p}} \) is anisotropic.

The \( H(\mathbb{F}) \)-conjugacy class of \( \alpha \) is fixed by \( \text{Gal}(\mathbb{F}/F) \). Denote this conjugacy class by \( O_H \); we view \( O_H \) as a homogeneous space for \( H \). We have \( (C_{\alpha,H^\sigma})_\mathbb{F} = C_{\alpha,H^\sigma} \) and \( (C_{\alpha,H})_\mathbb{F} = C_{\alpha,H} \) since \( \alpha \) is regular semisimple and \( H^{\text{der}} \) is simply connected. We therefore have a natural \( \sigma \)-equivariant embedding

\[
C_{\alpha,H^\sigma} \rightarrow (C_{\alpha,H})_\mathbb{F}
\]

(3.3.2)

where we define \( C_{\alpha,H}^m \) with respect to the homogeneous space \( O_H \) for \( H \). Thus (3.3.2) defines an \( F \)-form of \( C_{\alpha,H^\sigma} \). By assumption, \( \alpha^\xi \) is \( H^{\sigma}(\mathbb{F}) \)-conjugate to \( \alpha \) for all \( \xi \in \text{Gal}(\mathbb{F}/F) \). Using this fact, one checks that the \( F \)-form of \( C_{\alpha,H^\sigma} \) defined by (3.3.2) is isomorphic to the \( F \)-torus \( C_{\alpha,H^\sigma}^m \) defined with respect to \( O(\alpha) \) (see [Bo1, §1.7]). Thus, by (3.3.2), we have that

\[
C_{\alpha,H^\sigma}^m(R) = \{ g \in C_{\alpha,H}^m(R) : g^\sigma = g \}
\]

for commutative \( F \)-algebras \( R \). By the theorem of Kottwitz-Steinberg [K1, Theorem 4.1] the \( H(\mathbb{F}) \)-conjugacy class of \( \alpha \) contains an element \( \alpha' \in H(F) \). We therefore have a natural isomorphism of \( F \)-groups \( C_{\alpha,H}^m \cong C_{\alpha',H}^m \cong C_{\alpha',H} \) (see [Bo1, §1.7]). Since we assumed that \( \delta_0 \) was relatively \( \tau \)-elliptic, we have that \( (C_{\alpha',H}/Z_{H})_{F_\mathfrak{p}} \) is anisotropic, and hence the same is true of \( (C_{\alpha,H^\sigma}/Z_{H^\sigma})_{F_\mathfrak{p}} \), completing the proof of the proposition.

□
4. Matching of functions

In §3.2 we defined a notion of norm for relative classes. In this section we define a corresponding notion of matching functions. This necessitates the introduction of local orbital integrals and their stable analogues (these are defined in §4.1 and §4.2, respectively). We then define what we mean by matching of functions in §4.3. As in the usual trace formula, it is useful to have at our disposal local orbital integrals twisted by a character of a certain cohomology group; these relative $\kappa$-orbital integrals are defined in §4.4. They play a role in the prestabilization of (the regular elliptic part of) the twisted relative trace formula carried out in §7 and §8 below. In §4.5 and §4.6 we prove various matching statements.

4.1. Local orbital integrals: Definitions. Let $v$ be a place of $F$. Let $\Phi \in C^\infty_c(H(F_v))$ and let $\gamma \in H(F_v)$ be a relatively semisimple element. The (local) relative orbital integral is defined by

$$
RO_\gamma(\Phi) := \int_{H_\gamma(F_v) \backslash H^\sigma(F_v)^2} \Phi(h_1^{-1} \gamma h_2) \frac{dh_1 dh_2}{dt_\gamma},
$$

(4.1.1)

where $dh_1$ and $dt_\gamma$ are Haar measures on $H^\sigma(F_v)$ and $H_\gamma(F_v)$, respectively.

Similarly, let $f \in C^\infty_c(G(F_v))$ and let $\delta \in G(F_v)$ be a relatively $\tau$-semisimple element. The (local) twisted relative orbital integral is defined by

$$
TRO_\delta(f) := \int_{G_\delta(F_v) \backslash G^\sigma(F_v) \times G^\theta(F_v)} f(g_1^{-1} \delta g_2) \frac{dg_1 dg_2}{dt_\delta},
$$

(4.2.2)

where $dg_1$ and $dt_\delta$ are Haar measures on $G^\sigma(F_v)$, $G^\theta(F_v)$ and $G_\delta(F_v)$, respectively. These relative orbital integrals and twisted relative orbital integrals are all absolutely convergent [H].

4.2. Stable local orbital integrals. We assume the notation of the previous subsection. For any relatively semisimple $\gamma_0 \in H(F_v)$ we define the stable relative orbital integral by

$$
SRO_{\gamma_0}(\Phi) := \sum_{\gamma \sim \gamma_0} e(H_\gamma) RO_\gamma(\Phi, dt_\gamma),
$$

(4.2.1)

where $e(H_\gamma)$ denotes the Kottwitz sign as in [K2] and the sum is over a set of representatives for the set of relative classes in the stable relative class of $\gamma_0$.

Similarly, for a relatively $\tau$-semisimple $\delta_0 \in G(F_v)$ we define the stable twisted relative orbital integral by

$$
STRO_{\delta_0}(f) := \sum_{\delta \sim \delta_0} e(G_\delta) TRO_\delta(f, dt_\delta),
$$

(4.2.2)

where the sum is over a set of representatives for the set of relative $\tau$-classes in the stable relative $\tau$-class of $\delta_0$. In both cases, we assume that the measures $dt_\gamma$ (resp. $dt_\delta$) are compatible with respect to the inner twists given by (3.2.3) and (3.2.4), respectively. For the definition
of compatible, see, e.g., [K5, p. 631]. We note that the sums in (4.2.1) and (4.2.2) are finite since their cardinality is equal to the cardinality of the finite groups $D(H, H^\sigma \times H^\sigma; F_v)$ and $D(G, G^\sigma \times G^\sigma; F_v)$, respectively (see §3.2).

4.3. Matching of functions: Definition.

**Definition 4.1.** Two functions $\Phi \in C^\infty_c(H(F_v))$ and $f \in C^\infty_c(G(F_v))$ match on the relatively regular set (resp. match) if

$$SRO_\gamma(\Phi) = STRO_\delta(f)$$

whenever a relatively regular semisimple (resp. relatively semisimple) $\gamma \in H(F_v)$ is a norm of $\delta \in G(F_v)$,

$$SRO_\gamma(\Phi) = 0$$

whenever $\gamma$ is relatively regular semisimple (resp. relatively semisimple) and not a norm of a $\delta \in G(F_v)$, and

$$STRO_\delta(f) = 0$$

whenever $\delta$ is relatively $\tau$-regular semisimple (resp. relatively $\tau$-semisimple) and does not admit a norm $\gamma \in H(F_v)$.

In the definition, we assume that the implicit Haar measures are compatible with respect to the inner twist of (3.2.6)

**Remark.** The inner twists given by (3.2.3), (3.2.4), and (3.2.6) are not canonical, since they depend on choices of elements in $H^\sigma(\overline{K})$ and $G^\sigma(\overline{K})$. However, if $H_1$ and $H_2$ are inner forms of the same connected reductive $F$-group, then the notion of a measure on $H_1$ being compatible with a measure on $H_2$ is independent of the particular inner twist realizing the two groups as inner forms of each other (see [K5, p. 631]). Thus the ambiguity in (3.2.3), (3.2.4), and (3.2.6) is irrelevant for our purposes.

4.4. Local relative $\kappa$-orbital integrals. In this subsection we define relative versions of the $\kappa$-orbital integrals that occur in Langland’s and Kottwitz’s prestabilization of the usual trace formula [K4]. We use Labesse’s reformulation; see [La1] for notation and generalities regarding abelianized cohomology.

Let $v$ be a place of $F$ and let $I \leq H$ be a pair of connected reductive $F_v$-groups. Letting a superscript “$D$” denote the Pontryagin dual, we set notation for the finite abelian groups

$$\mathfrak{R}(I, H; F_v) := H^0_{ab}(F_v, I \backslash H)^D.$$  

(4.4.1)

Let $\gamma \in H(F_v)$ be relatively semisimple and let $\delta \in G(F_v)$ be relatively $\tau$-semisimple. For $\kappa_{H_v} \in \mathfrak{R}(H, H^\sigma \times H^\sigma; F_v)$ and $\Phi_v \in C^\infty_c(H(F_v))$ (resp. $\kappa_v \in \mathfrak{R}(G, G^\sigma \times G^\sigma; F_v)$ and
\[ f_v \in C_c^\infty(G(F_v)) \text{ we set} \]
\[
(4.4.2) \quad RO_{\gamma}^\kappa (\Phi_v) = \int_{H^0(F_v,H_\gamma \backslash H^{\sigma} \times H^{\sigma})} \langle \kappa_{H_v}, (\hat{h}_1, \hat{h}_2^{-1}) \rangle e((H_{h_1}^{-1} h_2)_{F_v}) \Phi_v(h_1^{-1} \gamma h_2) d\hat{h}_1 d\hat{h}_2,
\]
\[
TRO_{\delta}^\kappa (f_v) = \int_{H^0(F_v,G_\delta \backslash G^{\sigma} \times G^{\sigma})} \langle \kappa_v, (\hat{g}_1, \hat{g}_2^{-1}) \rangle e((G_{g_1}^{-1} \delta g_2)_{F_v}) f_v(g_1^{-1} \delta g_2) d\hat{g}_1 d\hat{g}_2.
\]

Here we use a system of compatible measures as in §4.2 to define the measures \(d\hat{h}_1 d\hat{h}_2\) on \(H^0(F_v,H_\gamma \backslash H^{\sigma} \times H^{\sigma})\) and \(d\hat{g}_1 d\hat{g}_2\) on \(H^0(F_v,G_\delta \backslash G^{\sigma} \times G^{\sigma})\), respectively (compare [La1, p. 42, 68]). Of course, the orbital integrals depend on this choice, but we will not encode it into our notation. In defining (4.4.2), we choose for each class \((\hat{h}_1, \hat{h}_2)\) an element \((h_1, h_2) \in H^{\sigma} \times H^{\sigma}(F_v)\) whose image in \(H^0(F_v,H_\gamma \backslash H^{\sigma} \times H^{\sigma})\) is \((\hat{h}_1, \hat{h}_2)\). Similarly, we choose for each class \((\hat{g}_1, \hat{g}_2)\) an element \((g_1, g_2) \in G^{\sigma} \times G^{\sigma}(F_v)\) whose image in \(H^0(F_v,G_\delta \backslash G^{\sigma} \times G^{\sigma})\) is \((\hat{g}_1, \hat{g}_2)\). The integrals do not depend on these choices. The symbol \(\langle \kappa_{H_v}, (\hat{h}_1, \hat{h}_2^{-1}) \rangle\) is the value of \(\kappa_v\) on the image of \((\hat{h}_1, \hat{h}_2^{-1})\) under the abelianization map, and similarly for \(\langle \kappa_v, (\hat{g}_1, \hat{g}_2^{-1}) \rangle\). In the case that \(\kappa_{H_v}\) (resp. \(\kappa_v\)) is trivial, we have
\[
RO_{\gamma}^\kappa (\Phi_v) = SRO_{\gamma} (\Phi_v)
\]
\[
TRO_{\delta}^\kappa (f_v) = STRO_{\delta} (f_v).
\]

4.5. Proof of the fundamental lemma: First case. Let \(v\) be a place of \(F\). For this subsection we assume that there is an isomorphism
\[
(4.5.1) \quad G_{F_v} \cong H_{F_v} \times H_{F_v}
\]
equivariant with respect to \(\sigma\) and intertwining \(\tau\) with \((x, y) \mapsto (y, x)\). For example, \(M/F\) could be split at \(v\) or (in the biquadratic case) \(ME/F\) could be split at \(v\) with \(E/F\) and \(M/F\) unramified and \(E/F\) nonsplit at \(v\). In the latter case we have an isomorphism
\[
(4.5.2) \quad E \otimes_F M \otimes_F F_v \cong E_v \oplus E_v
\]
equivariant with respect to the natural action of \(\sigma\) on both sides and intertwining \(\tau\) on the left with \((x, y) \mapsto (y, x)\) on the right.

Remark. By class field theory, at almost every place either \(E/F\) is split or \(E/F\) and \(M/F\) are unramified with \(E/F\) nonsplit at \(v\).

Definition 4.2. An element \(\gamma \in H(F_v)\) is a split norm of an element \(\delta = (\delta_1, \delta_2) \in G(F_v)\) if \(\gamma\) is in the relative class of \(\delta_1 \delta_2^{-\sigma}\).

The basic properties of this notion are summarized in the following lemma:

Lemma 4.3. If \(\gamma\) is a split norm of \(\delta\), then every element of the relative class of \(\gamma\) is a split norm of every element of the relative \(\tau\)-class of \(\delta\). If \(\gamma\) and \(\gamma'\) are split norms of \(\delta\), then \(\gamma\) and \(\gamma'\) are in the same relative class. If \(\delta\) and \(\delta'\) both have split norm \(\gamma\), then \(\delta\) and \(\delta'\) are in
the same relative \(\tau\)-class. Every \(\gamma \in H(F_v)\) is a split norm and every \(\delta \in G(F_v)\) has a split norm. If \(\gamma\) is relatively semisimple and \(\gamma\) is a split norm of \(\delta\), then it is a norm of \(\delta\).

**Proof.** The first three assertions are easy to verify. For the fourth, note that \((\gamma, 1) \in G(F_v)\) has split norm \(\gamma\) for any \(\gamma \in H(F_v)\). Conversely, \(\delta = (\delta_1, \delta_2)\) has split norm \(\delta_1\delta_2^{-\sigma}\).

We now prove the final statement of the lemma. Suppose \(\gamma\) is a split norm of \(\delta\). Write

\[
\delta\delta^{-\theta} = (\delta_1 \delta_2^{-\sigma}, \delta_2 \delta_1^{-\sigma}) = (x_\delta, x_\delta^{-\sigma})
\]

for some \(x_\delta \in H(F_v)\). At the expense of replacing \(\gamma\) with something in its relative class, we can and do assume that \(\gamma = x_\delta\). Thus it suffices to show that we can choose \(g \in H^\sigma(F_v)\) such that \(x_\delta x_\delta^{-\sigma} = g^{-1}x_\delta^{-\sigma}x_\delta g\), for then

\[
(1, g)^{-1}\delta\delta^{-\theta}(\delta\delta^{-\theta})^{-1}(1, g) = (1, g)^{-1}(x_\delta x_\delta^{-\sigma}, x_\delta^{-\sigma} x_\delta)(1, g) = (x_\delta x_\delta^{-\sigma}, x_\delta x_\delta^{-\sigma}),
\]

which implies \(\gamma = x_\delta\) is a norm of \(\delta\).

Since \(\gamma\) is relatively semisimple, there is a \(\sigma\)-split torus \(T_\sigma \leq H_{F_v}\) such that \(x_\delta x_\delta^{-\sigma} \in T_\sigma(F_v)\) \cite{Ri, Theorem 7.5}. Since the map \(x \mapsto xx^{-\sigma}\) coincides with \(x \mapsto x^2\) on \(T_\sigma\), we can and do choose \(x' \in T_\sigma(F_v)\) such that \(x'x'^{-\sigma} = x_\delta x_\delta^{-\sigma}\). The fiber of the map \(H \to Q\) of (3.1.2) over any point in \(Q(F_v)\) is a \(H^\sigma(F)\)-torsor, so we have \(x_\delta g' = x' \in T_\sigma(F)\) for some \(g' \in H^\sigma(F_v)\). Since \(T_\sigma\) is \(\sigma\)-stable, we have that \((x_\delta g')^{-\sigma}\) commutes with \(x_\delta g'\). In other words,

\[
x_\delta x_\delta^{-\sigma} = (x_\delta g)(x_\delta g)^{-\sigma} = (x_\delta g)^{-\sigma}(x_\delta g) = g^{-1}x_\delta^{-\sigma}x_\delta g.
\]

\(\square\)

If \(\delta = (\delta_1, \delta_2) \in G(F_v)\) then there is an isomorphism \(G(\delta_1, \delta_2) \to H_{\delta_1\delta_2^{-\sigma}}\) given on \(F_v\)-algebras \(R\) by

\[
\begin{align*}
G(\delta_1, \delta_2)(R) & \to H_{\delta_1\delta_2^{-\sigma}}(R) \\
(g_1, g_2, g_3, g_3^\sigma) & \mapsto (g_1, g_2)
\end{align*}
\]

and thus isomorphisms \(G_\delta \to H_\gamma\) for any split norm \(\gamma\) of \(\delta\). For the purposes of the following definition and lemma, fix a compact open subgroup \(K_H \leq H(F_v)\) that is \(\sigma\)-stable and let \(K = K_H \times K_H \leq G(F_v) \cong H(F_v) \times H(F_v)\).

**Definition 4.4.** Two functions \(\Phi \in C_c^\infty(H(F_v))\) and \(f \in C_c^\infty(G(F_v))\) split match if

\[
RO_\gamma(\Phi, dt_\gamma) = TRO_\delta(f, dt_\delta)
\]

whenever \(\gamma \in H(F_v)\) is a split norm of \(\delta \in G(F_v)\). Here the Haar measures \(dt_\gamma\) and \(dt_\delta\) are normalized so that the isomorphism \(G_\delta(F_v) \to H_\gamma(F_v)\) induced by (4.5.3) is measure-preserving and the Haar measure on \(H(F_v)\) (resp. \(G(F_v)\)) gives \(K_H\) (resp. \(K\)) volume 1.

For \(\Phi_i \in C_c^\infty(H(F_v))\) \((i \in \{1, 2\})\) we write \(\Phi_1 \times \Phi_2 \in C_c^\infty(G(F_v)) = C_c^\infty(H \times H(F_v))\) for the product function using (4.5.1). We have the following lemma:
Lemma 4.5. Let $\Phi_1, \Phi_2 \in C_c^\infty(H(F_v)//K_H)$ and write $f = \Phi_1 \times \Phi_2 \in C_c^\infty(G(F_v)//K)$ for the product function. Write $\Phi_2^{-\sigma}(g) := \Phi_2(g^{-\sigma})$. The functions $f$ and $\Phi_1 \star \Phi_2^{-\sigma}$ split match, where the $\star$ denotes convolution in $C_c^\infty(H(F_v)//K_H)$.

Proof. Let $\delta = (\delta_1, \delta_2) \in G(F_v)$. We have

$$
\int_{G_\delta(F_v)\setminus G^\sigma \times G^\sigma(F_v)} f(g^{-1}\delta h) dgdh
$$

(4.5.4)

$$
= \int_{H_\gamma(F_v)\setminus H^\sigma \times H^\sigma(F_v)} \left(\int_{H(F_v)} \Phi_1(g_1^{-1}\delta_1 h_1)\Phi_2(g_2^{-1}\delta_2 h_1^\sigma) dh_1\right) dg_1 dg_2
$$

$$
= \int_{H_\gamma(F_v)\setminus H^\sigma \times H^\sigma(F_v)} \Phi_1 \star \Phi_2^{-\sigma}(g_1^{-1}\delta_1 \delta_2^{-\sigma} g_2) dg_1 dg_2.
$$

Here we have used (4.5.1) to write $g = (g_1, g_2) \in G^\sigma(F_v) \cong H^\sigma(F_v) \times H^\sigma(F_v)$ and $h = (h_1, h_1^\sigma) \in G^\sigma(F_v)$ and we have used our assumption that the isomorphism $G_\delta(F_v) \overset{\sim}{\rightarrow} H_\gamma(F_v)$ given by (4.5.3) is measure preserving. With this in mind, the lemma follows from (4.5.4) and Lemma 4.3.

The inclusion $H \rightarrow G$ induces an $L$-map $^LH \rightarrow ^LG$. Assume for the moment that $H_F$ and $G_F$ are both quasi-split, let $K \leq G(F_v)$ and $K_H \leq H(F_v)$ be hyperspecial subgroups and let

$$
b : C_c^\infty(G(F_v)//K) \longrightarrow C_c^\infty(H(F_v)//K_H)
$$

be the base change homomorphism induced by the $L$-map above. One can check that with respect to the isomorphism (4.5.1) this homomorphism is given by

$$
b(f_1 \times f_2) = f_1 \star f_2.
$$

Thus in view of Lemma 4.3 and the remark at the end of §4.3 we have the following corollary:

Corollary 4.6. Let $K_H \leq H(F_v)$ be a $\sigma$-stable hyperspecial subgroup and let $K = K_H \times K_H \leq G(F_v) \cong H(F_v) \times H(F_v)$. Then if $f_1 \in C_c^\infty(H(F_v)//K_H)$ the functions $f_1 \times ch_{K_H}$ and $b(f_1 \times ch_{K_H}) = f_1$ match. □

4.6. Matching at the $E$-split places. Assume for the remainder of this section that we are in the biquadratic case. Let $v$ be a place of $F$. In this subsection we will always assume that $E/F$ splits at $v$. Thus there is an isomorphism

$$E \otimes_F F_v \cong F_v \oplus F_v
$$

(4.6.1)

intertwining $\sigma$ with $(x, y) \mapsto (y, x)$ and an isomorphism

$$H_{F_v} \cong H_{F_v}^\sigma \times H_{F_v}^\sigma
$$

(4.6.2)

intertwining $\sigma$ with $(x, y) \mapsto (y, x)$. Using this one easily deduces the following lemma:
Lemma 4.7. Let $\gamma \in H(F_v)$ and $\delta \in G(F_v)$ be relatively semisimple and relatively $\tau$-semisimple, respectively. Use (4.6.1) to write $\gamma \gamma^{-\sigma} = (y_\gamma, y_\gamma^{-1})$ and $\delta \delta^{-\theta} = (x_\delta, x_\delta^{-\tau})$. We have that $\gamma$ is a norm of $\delta$ if and only if $x_\delta x_\delta^{-\tau}$ is $G^\sigma(\widehat{F_v})$-conjugate to $y_\gamma$. □

If $\Phi_i \in C_c^\infty(H^\sigma(F_v))$ (resp. $f_i \in C_c^\infty(G^\sigma(F_v))$) for $i \in \{1, 2\}$, we let $\Phi_1 \times \Phi_2 \in C_c^\infty(H(F_v))$ (resp. $f_1 \times f_2 \in C_c^\infty(G(F_v))$) be the product functions defined using the isomorphism (4.6.2). For the definition of the $\mathfrak{K}_1$ groups in the following proposition we refer the reader to §7.2.

Proposition 4.8. Suppose that $\gamma \in H(F_v)$ is relatively semisimple and $\delta \in G(F_v)$ is relatively $\tau$-semisimple. Let $\Phi_i$ and $f_i$ be as above. Finally let $\kappa_H \in \mathcal{R}(H_\gamma, H^\sigma \times H^\sigma; F_v)_1$ and $\kappa \in \mathcal{R}(G_\delta, G^\sigma \times G^\theta; F_v)_1$. We then have

$$
RO^\kappa_H(\Phi_1 \times \Phi_2) = O^\kappa_H(\Phi_1 \ast \Phi_2^{-1})
$$

$$
TRO^\kappa(f_1 \times f_2) = O^\kappa_{x_\delta \times \gamma}(f_1 \ast f_2^{-\tau})
$$

where $\Phi_2^{-1}(h) := \Phi_2(h^{-1})$, $f_2^{-\tau}(h) := f_2(h^{-\tau})$, $\gamma \gamma^{-\sigma} = (y_\gamma, y_\gamma^{-1})$, and $\delta \delta^{-\theta} = (x_\delta, x_\delta^{-\tau})$.

In the proposition, we use notation as in [HL, §1.5] for the $\kappa$-orbital integrals $O^\kappa_{y_\gamma}$ and $O^\kappa_{x_\delta \times \gamma}$, and the $\mathfrak{K}_1$-groups are defined as in [La1, §1.8] (see also §7.2). Strictly speaking, the $\kappa_H$ in $O^\kappa_{y_\gamma}$ (resp. $\kappa$ in $O^\kappa_{x_\delta \times \gamma}$) should actually be the image of $\kappa_H$ (resp. $\kappa$) under

$$
\mathcal{R}(H_\gamma, H^\sigma \times H^\sigma; F_v)_1 \cong \mathcal{R}(C_{\gamma \gamma^{-\sigma}, H^\sigma}, H^\sigma \times H^\sigma; F_v)_1 \cong \mathcal{R}(C_{y_\gamma, H^\sigma}, H^\sigma; F_v)_1
$$

$$
\mathcal{R}(G_\delta, G^\sigma \times G^\theta; F_v)_1 \cong \mathcal{R}(C_{\delta \delta^{-\theta}, G^\sigma}, G^\sigma \times G^\theta; F_v)_1 \cong \mathcal{R}(C_{x_\delta, G^\sigma}, G^\sigma; F_v)_1
$$

where the left isomorphisms are induced by Lemma 3.1 and the right isomorphisms are due to the isomorphisms $C_{\gamma \gamma^{-\sigma}, H^\sigma} \cong C_{y_\gamma, H^\sigma}$ and $C_{\delta \delta^{-\theta}, G^\sigma} \cong C_{x_\delta, G^\sigma}$ induced by the projection of $H \cong H^\sigma \times H^\sigma$ (resp. $G \cong G^\sigma \times G^\sigma$) onto the first factor. However, we won’t burden the notation by indicating this. Also, to make the $\kappa_H$-orbital integrals well-defined we need to specify choices of Haar measures on $H^\sigma$, $G^\sigma$, and various centralizers, but, again, we will not incorporate this into the notation.

Proof. The statement involving relative orbital integrals can be recovered from the statement involving twisted relative orbital integrals by taking $\tau$ to be trivial. Therefore, it suffices to prove the statement regarding twisted relative orbital integrals.

Note that there is an isomorphism of $F_v$-group schemes $G_\delta \rightarrow C_{x_\delta, G^\sigma}$ given by

$$
G_\delta(R) \rightarrow C_{x_\delta, G^\sigma}(R)
$$

$$
((u, u), (h, h^\tau)) \mapsto u
$$

for $F_v$-algebras $R$ (compare Lemma 3.1). Moreover, for a given $\delta = (\delta_1, \delta_2) \in G(F_v)$ there is an isomorphism of affine $F_v$-schemes $G^\sigma \times G^\theta \rightarrow (G^\sigma)^2$ given by

$$
G^\sigma \times G^\theta(R) \rightarrow G^\sigma \times G^\sigma(R)
$$

$$
((u, u), (h, h^\tau)) \mapsto ((u, u), (u^{-1} \delta_2 h^\tau, u^{-1} \delta_2 h^\tau))
$$
for \( F_v \)-algebras \( R \). This maps \( G_\delta \) onto \( C_{x_\delta, G^\sigma}^r \times \{ (\delta_2, \delta_2) \} \), and thus a domain of integration for \( H^0(\mathcal{F}, G_\delta \backslash G^\sigma \times G^\theta) \) onto \( H^0(\mathcal{F}, C_{x_\delta, G^\sigma}^r \backslash G^\sigma) \times G^\sigma(F_v) \). This observation is used in one change of variables in the following computation:

\[
(4.6.6)
\]

\[
TRO_\delta(f_1 \times f_2)
= \int_{H^0(\mathcal{F}, G_\delta \backslash G^\sigma \times G^\theta)} \langle \kappa, (g_1, g_2) \rangle e(G_{g_1^{-1}g_2}) f_1 \times f_2 (g_1^{-1}g_2^{-1}) dg_1 dg_2
= \int_{H^0(\mathcal{F}, C_{x_\delta, G^\sigma}^r \backslash G^\sigma) \times G^\sigma(F_v)} \langle \kappa, (\hat{h}_1, \hat{h}_1), (\delta_2^{-1}h_1^r_1, \delta_2^{-1}h_1^r_2, \delta_2^{-1}h_2) \rangle e(C_{h_1^{-1}x_\delta h_1^r, G^\sigma}^r) f_1(h_1^{-1}h_1^r \delta_2^{-1}h_2^r) f_2(h_2^r) dh_2 \hat{h}_1.
\]

In the last equality we used the fact that there is an isomorphism of \( F_v \)-groups \( G_{g_1^{-1}g_2} \cong C_{g_1^{-1}g_2} \) for \((g_1, g_2) \in G^\sigma \times G^\theta(F_v) \) (compare (4.6.4)). If we temporarily denote the image of \( \kappa \) under (4.6.3) by \( \overline{\kappa} \), then

\[
(4.6.7)
\]

\[
\langle \kappa, (\hat{h}_1, \hat{h}_1), (\delta_2^{-1}h_1^r_1 \hat{h}_2, \delta_2^{-1}h_1 \hat{h}_2) \rangle = \langle \overline{\kappa}, \hat{h}_1 \rangle
\]

holds. From now on, we will omit the bar and just write \( \kappa \). With (4.6.7) in mind, the expression in (4.6.6) is equal to

\[
\int_{H^0(\mathcal{F}, C_{x_\delta, G^\sigma}^r \backslash G^\sigma) \times G^\sigma(F_v)} \langle \kappa, h_1 \rangle e((C_{h_1^{-1}x_\delta h_1^r, G^\sigma}^r) F_v) f_1(h_1^{-1}h_1^r \delta_2^{-1}h_2) f_2(h_2^r) dh_2 \hat{h}_1
= \mathcal{O}_{x_\delta r}^\sigma(f_1 \ast f_2^\tau).
\]

Assume now that \( v \) is nonarchimedean. If \( G_F^\sigma \) and \( H_F^\sigma \) are both unramified, let \( K' \leq G^\sigma(F_v) \) and \( K'_{H} \leq H^\sigma(F_v) \) be hyperspecial subgroups and let

\[
b : C_c^\infty(G^\sigma(F_v) // K') \to C_c^\infty(H^\sigma(F_v) // K'_{H})
\]

be the homomorphism induced by the base change homomorphism \( L^*H^\sigma \to LG^\sigma \).

**Corollary 4.9.** If \( v \) is nonarchimedean, then for every \( \Phi \in C_c^\infty(H(F_v)) \) there is a matching \( f \in C_c^\infty(G(F_v)) \) and conversely. If \( M \otimes_F F_v/F_v \) is unramified, \( G_F^\sigma \) and \( H_F^\sigma \) are unramified with hyperspecial subgroups \( K' \), \( K'_H \) as above, and \( \Phi_1 \in C_c^\infty(G^\sigma(F_v) // K') \) then \( \Phi_1 \times ch_{K'} \) matches \( b(\Phi_1) \times ch_{K'_H} \).

**Proof.** This follows immediately from Proposition 4.8, Lemma 4.7, [La1, Théorème 3.3.1] and [La1, Proposition 3.7.3].
5. Matching at the ramified places

We assume the notation of §4 regarding the definition of stable twisted relative orbital integrals and matching of functions. In §4 we provided a supply of matching functions for places of $F$ where various data were unramified. We now prove a weaker matching statement for the ramified places. It is contained in the following theorem, the main theorem of this section:

**Theorem 5.1.** Let $v$ be a place of $F$. If $f \in C_c^\infty(G(F_v))$ is supported in a sufficiently small neighborhood of a relatively $\tau$-regular semisimple $\delta \in G(F_v)$ admitting a norm $\gamma \in H(F_v)$ then there is a $\Phi \in C_c^\infty(H(F_v))$ that matches $f$ on the relatively regular set.

The proof will occupy the remainder of the section. Our approach is an adaptation of that in [La1, §3.1]. We also found the work of Rader-Rallis [RR] and Hakim [Hak2] useful.

5.1. Local constancy of the relative orbital integrals. Let $v$ be a place of $F$ and let $\delta \in G(F_v)$ be a relatively $\tau$-regular semisimple element. In this subsection we show that the relative orbital integrals of functions with support in a small neighborhood of $\delta$ can be viewed as a locally constant functions on a torus related to $\delta$. To ease notation, throughout this section we abbreviate $H = H_{F_v}, S = S_{F_v},$ etc.

We begin with the following lemma:

**Lemma 5.2.** If $\gamma \in H(F_v)$ is relatively regular semisimple, then the maximal $\sigma$-split subtorus of $C_{\gamma \gamma^{-\sigma}, H}$ is a maximal $\sigma$-split torus of $H$. If $\delta$ is relatively $\tau$-regular semisimple then the maximal $\sigma$-split subtorus of $C_{\delta \delta^{-\theta}, G}$ has the same dimension as a maximal $\sigma$-split torus of $H$.

We write $T_\gamma$ for the maximal $\sigma$-split subtorus of $C_{\gamma \gamma^{-\sigma}, H}$ and $\tilde{T}_\delta$ for the maximal $\sigma$-split subtorus of $C_{\delta \delta^{-\theta}, G}$.

**Proof.** The element $\gamma \gamma^{-\sigma}$ is contained in a maximal $\sigma$-split torus $T_\sigma$ of $H_{\mathcal{T}_v}$ [Ri, Theorem 7.5] which in turn is contained in a maximal $\sigma$-stable torus $T$ [He, Proposition 1.4]. Moreover, $T_\sigma$ is the unique maximal $\sigma$-split torus of $T$ (this follows from [Ri, Theorem 7.5]). Since $\gamma \gamma^{-\sigma}$ is regular semisimple, it is contained in a unique maximal torus, so $T = (C_{\gamma \gamma^{-\sigma}, H})_{\mathcal{T}_v}$, and it follows that $T_\sigma = T_{\gamma \mathcal{T}_v}$. Here we are implicitly using the fact that $T_\gamma$ is in fact defined over $F_v$, being the $\sigma$-split component of the $F_v$-torus $C_{\gamma \gamma^{-\sigma}, H}$. Thus $T_\gamma$ is a maximal $\sigma$-split torus.

We now prove the second claim. Choose an isomorphism $G_{\mathcal{T}_v} \cong H_{\mathcal{T}_v} \times H_{\mathcal{T}_v}$ equivariant with respect to $\sigma$ and intertwining $\tau$ with $(x, y) \mapsto (y, x)$. Using this isomorphism, write $\delta \delta^{-\theta} = (x_\delta, x_\delta^{-\sigma})$ for some $x_\delta \in H(\mathcal{T}_v)$. Our assumption that $\delta$ is relatively $\tau$-regular semisimple implies that $x_\delta$ is relatively semisimple. By the argument above, we see that
there is a (unique) maximal σ-split subtorus of $C_{\mu_\delta} \sigma$ which is moreover a maximal σ-split subtorus of $H$. On the other hand, there is a σ-equivariant isomorphism

$$(C_{\delta\delta} \sigma)_{\mathbb{F}} \to C_{\mu_\delta} \sigma$$

induced by the projection of $G_{\mathbb{F}} \cong H_{\mathbb{F}} \times H_{\mathbb{F}}$ onto the first factor. It follows that the maximal σ-split subtorus of $(C_{\delta\delta} \sigma)_{\mathbb{F}}$ has the same dimension as a maximal σ-split torus of $H_{\mathbb{F}}$. The maximal σ-split torus of $(C_{\delta\delta} \sigma)_{\mathbb{F}}$ is in fact defined over $F_v$ (compare [He, §1.3]), and the lemma follows.

Our first step to proving Theorem 5.1 is the following proposition:

**Proposition 5.3.** Suppose that $\delta_0 \in G(F_v)$ is relatively τ-regular semisimple. Let $V$ be a neighborhood of 1 in $\tilde{T}_{\delta_0}(F_v)$ and $W$ be a neighborhood of $\delta_0$ in $G(F_v)$.

1. Suppose that $f \in C_c^\infty(G(F_v))$ has support in $W$. If $V$ and $W$ are sufficiently small, then there is a function $\psi \in C_c^\infty(\tilde{T}_{\delta_0}(F_v))$ with support in $V$ such that if $\delta \in G(F_v)$ is τ-regular semisimple and its $G^\sigma \times G^\theta(F_v)$-orbit meets $W$, then

$$\delta = g_1^{-1} t \delta_0 g_2$$

with $t \in \tilde{T}_{\delta_0}(F_v)$, $(g_1, g_2) \in G^\sigma \times G^\theta(F_v)$, and

$$TRO_\delta(f) = \psi(t).$$

Moreover, if $t \in \tilde{T}_{\delta_0}(F_v)$ and $t \delta_0$ is in the stable relative τ-class of $\delta$, then

$$STRO_\delta(f) = \psi(t).$$

2. Conversely, if $\psi \in C_c^\infty(\tilde{T}_{\delta_0}(F_v))$ has support in $V$ and the neighborhoods $V$ and $W$ are sufficiently small, then there is an $f \in C_c^\infty(G(F_v))$ satisfying the identities of (1).

In [La1, §3.1], Labesse proves the analogue of Proposition 5.3 in the context of the usual trace formula. Our proof follows his closely. We require some preparatory lemmas:

**Lemma 5.4.** Assume $\delta_0$ is relatively τ-regular semisimple. There is an analytic subvariety $Y \subset G^\sigma \times G^\theta(F_v)$ that is symmetric (i.e. $(x, y) \in Y$ if and only if $(x^{-1}, y^{-1}) \in Y$) and a neighborhood $V$ of 1 in $\tilde{T}_{\delta_0}(F_v)$ such that the following are true:

1. The map

$$Y \times V \to G(F_v)$$

$$(x, y, t) \mapsto x^{-1} t \delta_0 y$$

is a diffeomorphism from $Y \times V$ to a neighborhood $W = W(Y, V)$ of $\delta_0 \in G(F_v)$.

2. If $(x, y) \in Y$, then $x^{-1} t \delta_0 y \in W$ and $t \in \tilde{T}_{\delta_0}(F_v)$ imply $t \in V$. Thus

$$\tilde{T}_{\delta_0}(F_v) \delta_0 \cap V = V \delta_0.$$
Proof. Choose a complement $n$ of $c = \text{Lie} C^r_{\delta_0^{-\theta},G^\sigma}(F_v)$ in $g^\sigma := \text{Lie} G^\sigma(F_v)$:

$$g^\sigma = n \oplus c.$$ 

Let $g^\theta := \text{Lie} G^\theta(F_v)$, let $\mathcal{O}$ be a neighborhood of 0 in $n \oplus g^\theta$, and let $Y = \text{Exp} \mathcal{O}$ be its image under the exponential map. Thus $Y \subset G^\sigma \times G^\theta(F_v)$ is an analytic subvariety. We claim that the analytic morphism

$$Y \times \tilde{T}_{\delta_0}(F_v) \longrightarrow G(F_v)$$

$$(g_1, g_2, t) \longmapsto (g_1^{-1}t\delta_0 g_2)$$

is locally an isomorphism at $(1, 1, 1)$.

In order to show this, we first explain how the work of Rader and Rallis implies that the analytic morphism

$$G^\sigma \times G^\theta(F_v) \times \tilde{T}_{\delta_0}(F_v) \longrightarrow G(F_v)$$

$$(g_1, g_2, t) \longmapsto g_1^{-1}t\delta_0 g_2$$

is a submersion whose fibers are of dimension $\dim_{F_v} C^r_{\delta_0^{-\theta},G^\sigma}$. If $\tau$ is trivial, then this follows from [RR, Theorem 3.4(1)]. Assume that $\tau$ is not trivial. Note that (5.1.2) fits into a commutative diagram

$$
\begin{array}{ccc}
G^\sigma \times G^\theta(F_v) \times \tilde{T}_{\delta_0}(F_v) & \longrightarrow & G(F_v) \\
\downarrow & & \downarrow \\
G^\sigma(F_v) \times \tilde{T}_{\delta_0}(F_v) & \longrightarrow & S(F_v) \\
(\text{left arrow}) & & (g \mapsto gg^{-\theta}) \\
(\text{right arrow}) & & \\
(\text{bottom arrow}) & & \\
\end{array}
$$

where the left arrow is the canonical projection and the top is (5.1.2). The vertical arrows are induced by smooth surjective maps of affine varieties both of relative dimension $\dim_{F_v} C^\theta$. Thus if we show that the bottom map is a submersion at $(1, 1, 1)$, it follows that the top is a submersion at $(1, 1, 1)$. Since the map $t \mapsto t^2$ on $\tilde{T}_{\delta_0}$ is an isogeny, in order to show that the bottom map of (5.1.3) is a submersion at $(1, 1)$ it suffices to show that the map

$$G^\sigma(F_v) \times \tilde{T}_{\delta_0}(F_v) \longrightarrow S(F_v)$$

$$(g_1, t) \longmapsto g_1^{-1}t\delta_0^{-\theta} g_1^\tau$$

is a submersion at $(1, 1)$.

To see this, let $M_v$ be $F_v$ if $v$ splits in $M/F$ and $M \otimes_F F_v$ otherwise. To prove that (5.1.4) is a submersion whose fibers are of dimension $\dim_{F_v} C^r_{\delta_0^{-\theta},G^\sigma}$, it suffices to show that

$$G^\sigma(M_v) \times \tilde{T}_{\delta_0}(M_v) \longrightarrow S(M_v)$$

$$(g_1, t) \longmapsto g_1^{-1}t\delta_0^{-\theta} g_1^\tau$$
is a submersion at \((1,1)\) of relative dimension \(\dim F_v C_{x_0}^\sigma,\theta,\sigma,\sigma, G^\sigma\). Choose an isomorphism \(G_{M_v} \cong H_{M_v} \times H_{M_v}\) equivariant with respect to \(\sigma\) and intertwining \(\tau\) with \((x,y) \mapsto (y,x)\). Using this isomorphism, write \(\delta_0 \delta_0^{-\sigma} = (x_0,x_0^{-\sigma})\) for some \(x_0 \in H(M_v)\) and let \(T_{x_0}\) be the largest \(\sigma\)-split torus in \(C_{x_0}^\sigma,\sigma, H\). There is a commutative diagram of analytic morphisms

\[
G^\sigma(M_v) \times \tilde{T}_{\delta_0}(M_v) \quad \xrightarrow{(u_1, u_2, t_1, t_2) \mapsto (u_1, u_2, t)} \quad S(M_v)
\]

\[
H^\sigma(M_v) \times H^\sigma(M_v) \times T_{x_0}(M_v) \quad \xrightarrow{(u_1, u_2, t) \mapsto u_1^{-1}tx_0u_2} \quad H(M_v)
\]

where the top arrow is \((5.1.5)\) and the vertical arrows are analytic isomorphisms induced by the isomorphism \(G(M_v) \cong H(M_v) \times H(M_v)\). Using Lemma 5.2 and [RR, Theorem 3.4(1)] (and the reference therein for the real case), we see that the bottom map is a submersion at \((1,1,1)\) of relative dimension \(\dim F_v C_{x_0}^\sigma,\sigma, H^\sigma\). It follows that the top vertical map of \((5.1.6)\) is a submersion of relative dimension \(\dim F_v C_{x_0}^\sigma,\sigma, H\). In view of the \(\sigma\)-equivariant isomorphism \(C_{\delta_0 \delta_0^{-\sigma}, G} \longrightarrow C_{x_0}^\sigma,\sigma, H\) induced by the projection of \(G_{M_v} \cong H_{M_v} \times H_{M_v}\) onto the first factor, this together with our comments above implies that \((5.1.2)\) is a submersion of relative dimension \(\dim F_v C_{\delta_0 \delta_0^{-\sigma}, G^\sigma}\), as claimed.

The analytic subvariety

\[
Y \times \tilde{T}_{\delta_0}(F_v) \subset G^\sigma \times G^\theta(F_v) \times \tilde{T}_{\delta_0}(F_v)
\]

is transverse to the subvariety

\[
X := \{(g_1, g_2, 1) : (g_1, g_2) \in G_{\delta_0}(F_v)\} \subset G^\sigma \times G^\theta(F_v) \times \tilde{T}_{\delta_0}(F_v)
\]

at \((1,1,1)\). The submersion \((5.1.2)\) maps \(X\) identically to \(\delta_0\). Our claim that \((5.1.1)\) is a local isomorphism follows. Thus we can and do choose \(O\) and \(V\) small enough so that the map

\[
Y \times V \longrightarrow G(F_v)
\]

induced by restricting \((5.1.1)\) is an isomorphism onto an open neighborhood \(W(Y, V)\) of \(\delta_0\). This proves (i).

Fix a neighborhood \(V_1\) of 1 in \(\tilde{T}_{\delta_0}(F_v)\) and an analytic subvariety \(Y_1 \subset G^\sigma \times G^\theta(F_v)\) small enough that (i) holds. For an analytic subvariety \(Y \subset Y_1\) and a neighborhood \(V \subset V_1\) of 1, let

\[
W := W(Y, V)
\]

be the image of \(Y \times V\) under \((5.1.1)\). Since \(\tilde{T}_{\delta_0}(F_v)\) is a closed subgroup of \(G(F_v)\), we can choose \(Y\) and \(V\) small enough so that

\[
\tilde{T}_{\delta_0}(F_v) \delta_0 \cap g_1^{-1}W g_2 \subset V_1 \delta_0
\]
Lemma 5.7. Suppose that $W \subset G(F_v)$ is a relatively compact neighborhood of $\delta_0$ and $V$ is a neighborhood of 1 in $\tilde{T}_{0}(F_v)$. If $V$ is sufficiently small, then there is a compact subset $\Omega \subset G^{\sigma} \times G^\theta(F_v)$ such that if
\[ g_1^{-1}t\delta_0g_2 \in W \]
with $t \in V$ then $(g_1, g_2) \in G_{\delta_0}(F_v)\Omega$.

Proof. Consider the continuous map
\[ A : G^{\sigma} \times G^\theta(F_v) \times \tilde{T}_{0}(F_v) \longrightarrow G(F_v) \]
\[ (g_1, g_2, t) \longmapsto g_1^{-1}t\delta_0g_2 \]
and let
\[ P : G^{\sigma} \times G^\theta(F_v) \times \tilde{T}_{0}(F_v) \longrightarrow G^{\sigma} \times G^\theta(F_v) \]
be the canonical projection. The lemma is equivalent to the statement that if $V$ and $W$ are sufficiently small (with $W$ relatively compact) then there exists a compact set $\Omega \subset G^{\sigma} \times G^\theta(F_v)$ such that $P \circ A^{-1}W \subset G_{\delta_0}(F_v)\Omega$. This latter statement is a consequence of [RR, Proposition 2.5] (and the reference therein in the real case); in loc. cit. one takes $M = G^{\sigma} \times G^\theta(F_v)$ and $H = G_{\delta_0}(F_v)$.

Lemma 5.6. Let $V$ be an open neighborhood of 1 in $\tilde{T}_{0}(F_v)$ and suppose $m, m' \in V$. If $V$ is sufficiently small and there is a $(g_1, g_2) \in G^{\sigma} \times G^\theta(F_v)$ such that $g_1^{-1}m\delta_0g_2 = m'\delta_0$, then $(g_1, g_2) \in G_{\delta_0}(F_v)$.

Proof. The proof of [La1, Lemme 3.1.4] easily adapts to our situation to prove the lemma. We only note that the analogue of [La1, Lemme 3.1.2] is trivial in our situation because $\delta_0$ is relatively $\tau$-regular semisimple, and the analogues of [La1, Lemme 3.1.1 and Lemme 3.1.3] are given by Lemma 5.4 and Lemma 5.5, respectively.

Lemma 5.7. Under the assumptions of Lemma 5.6, if $m'\delta_0$ and $m\delta_0$ are in the same stable relative $\tau$-class, then
\[ \overline{g}_1^{-1}m\overline{g}_1 = m' \]
for some $\overline{g}_1 \in C^\tau_{\delta_0\delta_0^{-\theta}F_1}(F_v)$. Hence $m = m'$.

Proof. Let $F_1/F_v$ be a finite field extension such that $C^\tau_{\delta_0\delta_0^{-\theta}F_1}$ is split. Then if $m, m'$ have the property that there exists $(\overline{g}_1, \overline{g}_2) \in G^{\sigma} \times G^\theta(F_v)$ satisfying $\overline{g}_1^{-1}m\delta_0\overline{g}_2 = m'\delta_0$, we can and do assume that $(\overline{g}_1, \overline{g}_2) \in G^{\sigma} \times G^\theta(F_1)$ (compare (3.2)). Applying Lemma 5.6 “over $F_1$” we have that $(\overline{g}_1, \overline{g}_2) \in G_{\delta_0}(F_1)$. Since $C^\tau_{\delta_0\delta_0^{-\theta}}$ is a torus, $\overline{g}_1$ commutes with $m$, which proves the last statement.
Lemma 5.8. For $Y, V,$ and $W(Y, V)$ as in Lemma 5.4, suppose $Y \subset U$ where $U$ is an open neighborhood of 1 in $G^\sigma \times G^\theta(F_v)$. If $U$ and $V$ are sufficiently small, then each

$$g_1^{-1}t\delta_0g_2 \in W(Y, V)$$

with $(g_1, g_2) \in G^\sigma \times G^\theta(F_v)$ and $t \in V$ satisfies $(g_1, g_2) \in G_\delta(F_v)Y$.

Proof. By our hypothesis and Lemma 5.4, we have

$$g_1^{-1}t\delta_0g_2 = y_1^{-1}t'\delta_0y_2$$

for some $(y_1, y_2) \in Y$ and $t' \in V$. By Lemma 5.6, if $U$ and $V$ are sufficiently small we have that $(g_1y_1^{-1}, g_2y_2^{-1}) \in G_\delta(F_v)$. □

With these lemmas in place, we can now prove Proposition 5.3:

Proof of Proposition 5.3. Choose a neighborhood $V$ of 1 in $\tilde{T}_\delta(F_v)$ and an analytic subvariety $Y \subset G^\sigma \times G^\theta(F_v)$ satisfying the conclusion of Lemma 5.4. Let $dg_1, dg_2,$ and $dt_\delta$ be Haar measures on $G^\sigma(F_v), G^\theta(F_v),$ and $G_\delta(F_v)$, respectively. In this proof we use these measures to define $TRO_\delta(f) = TRO_\delta(f, dt_\delta)$. There is a natural map

$$Y \rightarrow G_\delta(F_v) \backslash G^\sigma \times G^\theta(F_v);$$

let $d\mu$ be the measure on $Y$ that is the pullback of the measure $\frac{dg_1dg_2}{dt_\delta}$ with respect to this map. Suppose that $f \in C_c(G(F_v))$ has support in $W := W(Y, V)$ and that $Y$ and $V$ are sufficiently small. For each $t \in \tilde{T}_\delta(F_v)$, define

$$\psi(t) := \int_Y f(g_1^{-1}t\delta_0g_2)d\mu(g_1, g_2).$$

By Lemma 5.4 the function $\psi$ on $\tilde{T}_\delta(F_v)$ is smooth and compactly supported (with support in $V$). Since $G_\delta = G_\delta$ we have

$$TRO_\delta(f) = \int_{G_\delta(F_v) \backslash G^\sigma \times G^\theta(F_v)} f(g_1^{-1}t\delta_0g_2) \frac{dg_1dg_2}{dt_\delta}$$

for some $t \in V$. In view of Lemma 5.8 this implies

$$TRO_\delta(f) = \int_Y f(g_1^{-1}t\delta_0g_2)d\mu(g_1, g_2)$$

and thus

$$TRO_\delta(f) = \psi(t).$$

The assertion involving stable twisted relative orbital integrals follows from Lemma 5.7, and this completes the proof of (1).

For the proof of (2), suppose that we are given $\psi$ with support in $V$. Each $\delta \in W$ can be written in a unique fashion as

$$\delta = g_1^{-1}t\delta_0g_2$$
with \((g_1, g_2) \in Y\) and \(t \in V\). Define 
\[(J^\beta \psi)(\delta) = \beta(g_1, g_2)\psi(t)\]
where \(\beta \in C_c^\infty(Y)\) is chosen so that
\[\int_Y \beta(g_1, g_2) d\mu(g_1, g_2) = 1.\]
Setting \(f = J^\beta \psi\), statement (2) follows from the observation that
\[\int_Y J^\beta \psi = \psi.\]

5.2. **Proof of Theorem 5.1.** For this entire subsection we assume the hypotheses of Theorem 5.1. We assume \(f\) is supported in a neighborhood \(W = W(Y, V)\) of a relatively \(\tau\)-regular semisimple element \(\delta_0\), with \(Y\) and \(V\) as in Lemma 5.4. With notation and assumptions as in Proposition 5.3, we have that
\[\text{STRO}_\delta(f) = 0\]
if the stable class of \(\delta\) does not meet \(\widetilde{T}_{\delta_0}(F_v)\delta_0\), and
\[\text{STRO}_\delta(f) = \psi(t)\]
if \(\delta\) is in the stable class of \(t\delta_0\) with \(t \in \widetilde{T}_{\delta_0}(F_v)\).

In a sufficiently small neighborhood of the identity in \(\widetilde{T}_{\delta_0}(F_v)\), the map \(t \mapsto t^2\) is an isomorphism that preserves conjugacy classes. Thus we can and do choose a function \(\psi_1 \in C_c^\infty(\widetilde{T}_{\delta_0}(F_v))\) with support in a small neighborhood \(V_1\) of the identity such that
\[\psi(t) = \psi_1(t^2).\]

By shrinking \(V\) if necessary, we can make \(V_1\) as small as we wish.

Assume that \(\delta_0\) has norm \(\gamma_0 \in H(F_v)\). Thus \(C^\tau_{\delta_0\delta_0^{-\sigma},G}\) and \(C^\tau_{\gamma_0\gamma_0^{-\sigma},H}\) are inner twists of each other, and the inner twist can be defined by an element of \(H^\sigma(\overline{F_v})\) (compare (3.2.6)). Since \(\delta_0\) is relatively \(\tau\)-regular, \(C^\tau_{\delta_0\delta_0^{-\sigma}}\) is a torus, and thus the inner twist induces a \(\sigma\)-equivariant isomorphism
\[(5.2.1)\]
\[B : C^\tau_{\delta_0\delta_0^{-\sigma},G} \rightarrow C^\tau_{\gamma_0\gamma_0^{-\sigma},H}.\]

Note that \(\widetilde{T}_{\delta_0}\) is a maximal \(\sigma\)-split torus of \(C^\tau_{\delta_0\delta_0^{-\sigma},G^*}\). Since \(T_{\gamma_0}\) and \(\widetilde{T}_{\delta_0}\) have the same dimension by Lemma 5.2, the isomorphism (5.2.1) induces another isomorphism
\[B : \widetilde{T}_{\delta_0} \rightarrow T_{\gamma_0}\]
such that for \(F_v\)-algebras \(R\) one has \(B(g_1^{-1}tg_1) = B(g_1)^{-1}B(t)B(g_1)\) for \(g_1 \in C^\tau_{\delta_0\delta_0^{-\sigma},G^*}(R)\) and \(t \in \widetilde{T}_{\delta_0}(R)\). Set \(\psi_2 := \psi_1 \circ B^{-1} \in C_c^\infty(T_{\gamma_0}(F_v))\). Then \(\psi_2\) has support in \(B(V_1)\), and
\[(5.2.2)\]
\[\psi_1(t^2) = \psi_2(B(t^2)).\]
We note that $B(t^2)\gamma_0$ is a norm of $t\delta_0$ (this is the reason for employing the squaring map above).

Invoking Proposition 5.3(2), we shrink $\mathcal{V}$ and $\mathcal{V}_1$ if necessary and choose a function $\Phi \in C^\infty_c(H(F_v))$ such that

$$SRO_\gamma(\Phi) = 0$$

if the stable class of $\gamma$ does not meet $T_{\gamma_0}(F_v)\gamma_0$, and

$$SRO_\gamma(\Phi) = \psi_2(t_2)$$

if $t_2\gamma_0$ and $\gamma$ are in the same stable class. This implies the assertion of the theorem. \hfill \Box

6. Spherical characters

In this section we introduce the notion of a relatively $\tau$-regular and relatively $\tau$-elliptic representation of a reductive group over a local field. The first of these notions was used in the statement of Theorem 1.1, and we believe the second to be of interest as well. Let $\Pi_v$ be an irreducible admissible representation of $G(F_v)$ with space $V_{\Pi_v}$ and choose

$$\Lambda = \sum_i \lambda_i \otimes \lambda_i^\vee \in \text{Hom}_{G^\sigma(F_v)}(V_{\Pi_v}, \mathbb{C}) \otimes \text{Hom}_{G^\theta(F_v)}(V_{\Pi_v^\vee}, \mathbb{C});$$

here $\mathbb{C}$ is the trivial representation and $\Pi_v^\vee$ is the contragredient representation acting on $V_{\Pi_v^\vee}$. The linear form $\Lambda$ defines a distribution (i.e. a linear map)

$$(6.0.1) \quad \Theta_\Lambda : C^\infty_c(G(F_v)) \longrightarrow \mathbb{C} \quad f_v \mapsto \sum_i \langle \Pi_v(f_v)\lambda_i, \lambda_i^\vee \rangle.$$

A spherical matrix coefficient (of $\Pi_v$) is a distribution attached to $\Lambda$ in this manner (compare [Hak2]). If the extension $M/F$ is trivial (so $H = G$ and $G^\sigma = G^\theta = H^\sigma$) then the spherical matrix coefficient $\Theta_\Lambda$ is representable by a locally constant function on the relatively regular subset of $G(F_v) = H(F_v)$ by [Hak2, Lemma 6]. We denote this function by $\Theta_\Lambda$ as well. The authors suspect that the same result is true when $\tau$ is nontrivial, but we will not prove this.

Definition 6.1. An admissible representation $\Pi_v$ of $G(F_v)$ is relatively $\Lambda$-regular if there is a function $f \in C^\infty_c(G(F_v))$ supported in the set of relatively $\tau$-regular elements of $G(F_v)$ admitting norms in $H(F_v)$ such that

$$\Theta_\Lambda(f) \neq 0.$$

It is relatively $\tau$-regular if it is relatively $\Lambda$-regular for all nonzero

$$\Lambda \in \text{Hom}_{G^\sigma(F_v)}(V_{\Pi_v}, \mathbb{C}) \otimes \text{Hom}_{G^\theta(F_v)}(V_{\Pi_v^\vee}, \mathbb{C}).$$
Definition 6.2. An admissible representation $\Pi_v$ of $G(F_v)$ is relatively $\Lambda$-elliptic if there is a function $f \in C^\infty_c(G(F_v))$ supported in the set of relatively $\tau$-elliptic semisimple elements of $G(F_v)$ admitting norms in $H(F_v)$ such that

$$\Theta_\Lambda(f) \neq 0.$$ 

It is relatively $\tau$-elliptic if it is relatively $\Lambda$-elliptic for all nonzero $\Lambda \in \text{Hom}_{G_\sigma}(F_v, \mathbb{C}) \otimes \text{Hom}_{G_\theta}(F_v, \mathbb{C})$.

If $\tau$ is trivial then we omit it from notation, writing relatively regular for relatively $\tau$-regular. The analogous convention with regular replaced by elliptic will also be in force. If $\tau$ is trivial the norm map is the identity map so the condition on elements admitting norms can be omitted.

Remark. In certain circumstances one can use the simple twisted relative trace formula of [H] to prove the existence of relatively $\tau$-regular (resp. $\tau$-semisimple) representations.

It is well known that the character of an irreducible admissible representation does not vanish on the regular semisimple set. Thus if $\tau$ is trivial, $G := H = H^\sigma \times H^\sigma$ and $\sigma : H \to H$ is the automorphism switching the two factors every irreducible admissible representation is relatively regular. We do not know if the same statement is true in general, and one has to be cautious given [RR, §4]. However, it seems likely that in the settings of interest to this paper every irreducible admissible representation arising as a local factor of a cuspidal automorphic representation that is both $G^\sigma$ and $G^\theta$-distinguished is relatively $\tau$-regular.

7. Prestabilization of a single stable relative orbital integral

In this section, following work of Langlands, Kottwitz, Shelstad, and Labesse, we define stable relative and stable twisted relative global orbital integrals and show how they decompose into a sum of global relative $\kappa$-orbital integrals. The main result is Proposition 7.2. As anyone familiar with the usual (not relative) stable trace formula could guess, the reason for introducing the relative $\kappa$-orbital integrals is that they factor into local $\kappa$-orbital integrals. This makes it possible to apply the local matching theory developed in §3 and §4. Our treatment follows [La1], and we refer to loc. cit. for notation involving abelianized cohomology of reductive groups and quotients. We emphasize that we do not attempt to write the $\kappa$-orbital integrals given below in terms of stable relative orbital integrals on other groups; this is why the section is entitled “Prestabilization...” instead of “Stabilization...” In §8 below, we show how to collect the relatively elliptic terms of the relative trace formula together.

We should note that in the biquadratic, non-twisted case, a stabilization dependent on various conjectural fundamental lemmas was given by Flicker in [Fl4], together with a conjectural definition of relative transfer factors.
7.1. **Global relative orbital integrals.** Let $\Phi \in C^\infty_c(H(\mathbb{A}_F))$, $f \in C^\infty_c(G(\mathbb{A}_F))$. Moreover let $\gamma \in H(F)$ (resp. $\delta \in G(F)$) be a relatively semisimple element (resp. relatively $\tau$-semisimple element). We define the (global) relative orbital integral

\[
RO_\gamma(\Phi) := \int_{H_\gamma(\mathbb{A}_F)/H^s(\mathbb{A}_F)^2} \Phi(h_1^{-1}h_2) \frac{dh_1 dh_2}{dt_\gamma},
\]

where $dh_1 = \otimes'_v dh_{i,v}$ and $dt_\gamma = \otimes'_v dt_{\gamma,v}$ are Haar measures on $H^s(\mathbb{A}_F)$ and $H_\gamma(\mathbb{A}_F)$, respectively. Similarly, we define the (global) twisted relative orbital integral

\[
TRO_\delta(f) := \int_{G_\delta(\mathbb{A}_F)/G^s \times G^s(\mathbb{A}_F)} f(g_1^{-1}g_2) \frac{dg_1 dg_2}{dt_\delta},
\]

where $dg_1 = \otimes'_v dg_{i,v}$ and $dt_\delta := \otimes'_v dt_{\delta,v}$ are Haar measures on $G^s(\mathbb{A}_F)$ and $G_\delta(\mathbb{A}_F)$, respectively. If $\Phi = \otimes'_v \Phi_v$ is factorable then

\[
RO_\gamma(\Phi, dt_\gamma) = \prod_v RO_{\gamma_v}(\Phi_v, dt_{\gamma,v}).
\]

If $f = \otimes'_v f_v$ is factorable then

\[
TRO_\delta(f, dt_\delta) = \prod_v TRO_{\delta_v}(f_v, dt_{\delta,v}).
\]

Let $\gamma_0 \in H(F)$ and $\delta_0 \in G(F)$ be relatively semisimple and relatively $\tau$-semisimple, respectively. The (global) stable relative orbital integral is

\[
SRO_{\gamma_0}(\Phi) := \sum_{\gamma \sim \gamma_0} RO_\gamma(\Phi, dt_\gamma)
\]

where the sum is over relatively semisimple $\gamma \in H(F)$ in the same stable relative class as $\gamma_0$. The (global) stable twisted relative orbital integral is

\[
STRO_{\delta_0}(f) := \sum_{\delta \sim \delta_0} TRO_\delta(f, dt_\delta)
\]

where the sum is over relatively $\tau$-semisimple $\delta \in G(F)$ in the same stable relative $\tau$-class as $\delta_0$. Here we assume that the $dt_\gamma = \otimes'_v dt_{\gamma,v}$ (resp. $dt_\delta = \otimes'_v dt_{\delta,v}$) are compatible in the sense that for each $v$ the $dt_{\gamma,v}$ (resp. $dt_{\delta,v}$) are compatible as in §4.3.

In analogy with (4.4.1), for a pair of (connected) reductive $F$-groups $I \leq H$ we set notation for the abelian group

\[
\mathcal{R}(I, H; F) := H^0_{ab}(\mathbb{A}_F/F, I \backslash H)^D.
\]

For each place $v$ there is a localization map

\[
\mathcal{R}(I, H; F) \longrightarrow \mathcal{R}(I, H; F_v)
\]

defined as the dual of

\[
H^0_{ab}(F_v, I \backslash H) \longrightarrow H^0_{ab}(\mathbb{A}_F, I \backslash H) \longrightarrow H^0_{ab}(\mathbb{A}_F/F, I \backslash H).
\]
Let $\Phi = \otimes_v'\Phi_v \in C_c^\infty(H(\mathbb{A}_F))$ and $f = \otimes_v f_v \in C_c^\infty(G(\mathbb{A}_F))$ be factorable, and let $\gamma \in H(F)$ (resp. $\delta \in G(F)$) be relatively semisimple (resp. relatively $\tau$-semisimple). Finally, let $\kappa_H \in \mathcal{R}(H^\sigma, H^\sigma \times H^\sigma; F)$ and $\kappa \in \mathcal{R}(G_\delta, G^\sigma \times G^\sigma; F)$. We then set

\begin{equation}
RO^\kappa_H(\Phi) := \prod_v RO^\kappa_H(\Phi_v)
\end{equation}

\begin{equation}
TRO^\kappa_\delta(f) := \prod_v TRO^\kappa_{\delta_v}(f_v),
\end{equation}

whenever this product is well-defined (i.e. convergent). The following proposition ensures convergence:

**Proposition 7.1.** Let $\gamma_0 \in H(F)$ (resp. $\delta_0 \in G(F)$) be relatively regular semisimple (resp. relatively $\tau$-regular semisimple) and let $\kappa_H \in \mathcal{R}(H_{\gamma_0}, H^\sigma \times H^\sigma; F)$ (resp. $\kappa \in \mathcal{R}(G_{\delta_0}, G^\sigma \times G^\sigma; F)$). Moreover, let $\Phi = \otimes_v'\Phi_v \in C_c^\infty(H(\mathbb{A}_F))$ and $f = \otimes_v f_v \in C_c^\infty(G(\mathbb{A}_F))$. There is a finite set $S$ of places of $F$ such that if $v \notin S$ then $RO^\kappa_{\gamma_0}(\Phi_v) = 1$ (resp. $TRO^\kappa_{\delta_v}(f_v) = 1$).

We note that this is a weak relative analogue of the results of [K4, §7].

**Proof.** Note that $(G_\delta)_{F_v} = G_{\delta_{F_v}}$ is quasi-split for almost all $v$, and hence $e(G_{\delta_{F_v}}) = 1$ for almost all $v$, and the character $\kappa_v$ is trivial on the intersection of the $G^\sigma \times G^\sigma$-orbit of $\delta_v$ and the support of $f_v$ for almost all $v$ by the definition of the (restricted direct) topology on $H^0_{ab}(\mathbb{A}_F, G_\gamma \setminus G^\sigma \times G^\sigma)$ [La1, §1.4-1.8] and the proof of [H, Proposition 3.4]. With this in mind, the proposition follows immediately from [H, Proposition 3.2] and the proof of [H, Proposition 3.4].

### 7.2. Some cohomology groups

In this subsection we collect notation for some Galois cohomology groups that will be used in the following subsections. Let $v$ be a place of $F$ and let $I \leq H$ be a pair of connected reductive $F_v$-groups. Set

\begin{equation}
\mathcal{E}(I, H; F_v) := \ker \left[ H^1_{ab}(F_v, I) \to H^1_{ab}(F_v, H) \right].
\end{equation}

There is a natural map

$$H^0_{ab}(F_v, I \setminus H) \to \mathcal{E}(I, H; F_v)$$

induced by the long exact sequence attached to the crossed Gal($\overline{F}_v/\overline{F}_v$)-module $I(\overline{F}_v) \to H(\overline{F}_v)$ [La1, p. 20]. The image of the dual map

$$\mathcal{E}(I, H; F_v)^D \to \mathcal{R}(I, H; F_v)$$

is denoted $\mathcal{R}(I, H; F_v)_1$. Similarly, if $I \leq H$ is a pair of connected reductive $F$-groups, write

$$\mathcal{E}(I, H; \mathbb{A}_F / F) := \ker \left[ H^0_{ab}(\mathbb{A}_F, H) \to H^0_{ab}(\mathbb{A}_F / F, I \setminus H) \right].$$

There is a natural quotient map

$$H^0_{ab}(\mathbb{A}_F / F, I \setminus H) \to \mathcal{E}(I, H; \mathbb{A}_F / F).$$
The image of the dual map

\[ \mathfrak{C}(I, H; \mathbb{A}_F/F)^D \rightarrow \mathfrak{R}(I, H; F) \]

is denoted \( \mathfrak{R}(I, H; F)_1 \). The localization map (7.1.7) induces a homomorphism

\[ \mathfrak{R}(I, H; F)_1 \rightarrow \prod_v \mathfrak{R}(I, H; F_v)_1 \]

(compare [La1, p. 43]). The kernel of this map is denoted \( \mathfrak{R}(I, H; F)_0 \).

7.3. Prestabilization of a single relatively elliptic term. For a reductive \( F \)-group \( H \), write \( \tau(H) \) for the Tamagawa number of \( H \) (this \( \tau \) should not be confused with the Galois automorphism \( \tau \) from above). Finally, for a pair of reductive \( F \)-groups \( I \) and \( H \), write

\[ d(I, H) := \# \text{coker } [H^1_{ab}(\mathbb{A}_F/F, I) \rightarrow H^1_{ab}(\mathbb{A}_F/F, H)] \] (7.3.1)

The main result of this section is the following adaptation of the work of Langlands, Kottwitz, and Labesse [L2], [K3], [K4], [La1] to our situation:

**Proposition 7.2.** Let \( \Phi = \otimes_v \Phi_v \in C^\infty_c(H(\mathbb{A}_F)) \) and \( f = \otimes_v f_v \in C^\infty_c(G(\mathbb{A}_F)) \) be factorable. If \( \gamma \in H(F) \) is relative regular and relatively elliptic then

\[ SRO_\gamma(\Phi) = \frac{\tau(H^\sigma \times H^\sigma)}{\tau(H_\gamma) d(H_\gamma, H^\sigma \times H^\sigma)} \sum_{\kappa_H} RO^\kappa_H(\Phi) \]

\[ = \frac{\tau(H^\sigma \times H^\sigma)}{\tau(H_\gamma) d(H_\gamma, H^\sigma \times H^\sigma)} \sum_{\kappa_H} \prod_v RO^\kappa_{\gamma_v}(\Phi_v) \]

where the sum is over \( \kappa_H \in \mathfrak{R}(H_\gamma, H^\sigma \times H^\sigma; F)_1 \).

Similarly, if \( \delta \in G(F) \) is relatively \( \tau \)-regular and relatively elliptic then

\[ STRO_\delta(f) = \frac{\tau(G^\sigma \times G^\theta)}{\tau(G_\delta) d(G_\delta, G^\sigma \times G^\theta)} \sum_{\kappa} TRO^\kappa_\delta(f) \]

\[ = \frac{\tau(G^\sigma \times G^\theta)}{\tau(G_\delta) d(G_\delta, G^\sigma \times G^\theta)} \sum_{\kappa} \prod_v TRO^\kappa_{\gamma_v}(f_v) \]

where the sum is over \( \kappa \in \mathfrak{R}(G_\gamma, G^\sigma \times G^\theta; F)_1 \).

**Proof.** We begin by recalling that \( H_\gamma \) and \( G_\delta \) are connected, and hence the groups

\[ \mathfrak{R}(H_\gamma, H^\sigma \times H^\sigma; F)_1 = \mathfrak{C}(H_\gamma, H^\sigma \times H^\sigma; \mathbb{A}_F/F)^D \]

\[ \mathfrak{R}(G_\delta, G^\sigma \times G^\theta; F)_1 = \mathfrak{C}(G_\delta, G^\sigma \times G^\theta; \mathbb{A}_F/F)^D \]

are finite [La1, Proposition 1.8.4]. Moreover, the \( \kappa \)-orbital integrals converge by Proposition 7.1. With these observations in mind, the proof is a standard consequence of the Fourier transform on a finite group. In more detail, one combines the first exact sequence on [La1,
8. Grouping relatively elliptic terms

In this section, we group together the relatively elliptic and relatively $\tau$-elliptic portions of the relative trace formula and twisted relative trace formula, respectively.

8.1. Haar measures. Recall the Harish-Chandra subgroups $^1H(\mathbb{A}_F)$ and the central subgroups $A_H \leq H(F \otimes_{\mathbb{Q}} \mathbb{R})$ of $\S 2.3$. For every $\gamma \in H(\mathbb{A}_F)$ and $\delta \in G(\mathbb{A}_F)$ write

$$^2H^\sigma(\mathbb{A}_F) := H^\sigma(\mathbb{A}_F) \cap 1H(\mathbb{A}_F)$$

$$^2G^\sigma(\mathbb{A}_F) := G^\sigma(\mathbb{A}_F) \cap 1G(\mathbb{A}_F)$$

$$^2G^\theta(\mathbb{A}_F) := G^\theta(\mathbb{A}_F) \cap 1G(\mathbb{A}_F)$$

$$^2H_\gamma(\mathbb{A}_F) := H_\gamma(\mathbb{A}_F) \cap 1H(\mathbb{A}_F) \times 1H(\mathbb{A}_F)$$

$$^2G_\delta(\mathbb{A}_F) := G_\delta(\mathbb{A}_F) \cap 1G(\mathbb{A}_F) \times 1G(\mathbb{A}_F).$$

Moreover, write

$$A_H^\gamma := H^\sigma(\mathbb{F} \otimes_{\mathbb{Q}} \mathbb{R}) \cap A_H$$

$$A_G^\gamma := G^\sigma(\mathbb{F} \otimes_{\mathbb{Q}} \mathbb{R}) \cap A_G$$

and

$$A := \{(x, x) \in A_H^\gamma \times A_H^\gamma\}$$

$$\tilde{A} := \{(z, z) \in A_G^\gamma \times A_G^\gamma : z \in A_G^\gamma \cap A_G^\gamma\}.$$

We then have decompositions

$$H_\gamma(\mathbb{A}_F) \backslash H^\sigma(\mathbb{A}_F) \times H^\sigma(\mathbb{A}_F) \cong (A \backslash A_H^\gamma \times A_H^\gamma) \times (^2H_\gamma(\mathbb{A}_F) \backslash ^2H^\sigma(\mathbb{A}_F) \times ^2H^\sigma(\mathbb{A}_F))$$

$$G_\delta(\mathbb{A}_F) \backslash G^\sigma(\mathbb{A}_F) \times G^\sigma(\mathbb{A}_F) = (\tilde{A} \backslash A_G^\gamma \times A_G^\gamma) \times (^2G_\delta(\mathbb{A}_F) \backslash ^2G^\sigma(\mathbb{A}_F) \times ^2G^\theta(\mathbb{A}_F)).$$

We now specify a choice of Haar measure on all of the groups appearing in (8.1.1), at least if $\gamma$ is relatively elliptic (resp. $\delta$ is relatively $\tau$-elliptic). Whenever a reductive $F$-group $H$ appears, we give $H(\mathbb{A}_F)$, $A_H$, and $^1H(\mathbb{A}_F)$ the measures that are used in the definition of the Tamagawa number $\tau(H)$. We then fix, once and for all, measures $dz_1 = dz_2$ for $A_H^\gamma$, $d\tilde{z}$ for $A_G^\gamma$ and $d\tilde{z}_\theta$ for $A_G^\theta$, and stipulate that the isomorphisms

$$^2H^\sigma(\mathbb{A}_F) \cong A_H^\sigma/A_H^\gamma \times ^1H^\sigma(\mathbb{A}_F)$$

$$^2G^\sigma(\mathbb{A}_F) \cong A_G^\sigma/A_G^\gamma \times ^1G^\sigma(\mathbb{A}_F)$$

$$^2G^\theta(\mathbb{A}_F) \cong A_G^\theta/A_G^\gamma \times ^1G^\theta(\mathbb{A}_F)$$.
are measure preserving. Notice that if $\gamma$ is relatively elliptic (resp. $\delta$ is relatively $\tau$-elliptic) then

\[ 2H_\gamma(\mathbb{A}_F) = H_\gamma(\mathbb{A}_F) \]
\[ 2G_\delta(\mathbb{A}_F) = G_\delta(\mathbb{A}_F). \]

By our earlier convention, we have already endowed $2H_\gamma(\mathbb{A}_F)$, $2G_\delta(\mathbb{A}_F)$, $A = A_{H_\gamma}$ and $\tilde{A} = A_{G_\delta}$ with measures. Altogether, this endows all of the groups occurring in (8.1.1) with measures. Thus $2H_\gamma(\mathbb{A}_F)$ and $2G_\delta(\mathbb{A}_F)$ are given the unique Haar measures such that if $\gamma$ is relatively elliptic and $\delta$ is relatively $\tau$-elliptic then

\[ \text{vol}(H_\gamma(F) \setminus 2H_\gamma(\mathbb{A}_F)) = \tau(H_\gamma) \]
\[ \text{vol}(G_\delta(F) \setminus 2G_\delta(\mathbb{A}_F)) = \tau(G_\delta). \]

For the rest of this paper, we use these choices of measures when we form relative orbital integrals and twisted relative orbital integrals. These measures will be compatible for the same reason that the Tamagawa measures in the usual trace formula are compatible, namely that the Tamagawa numbers of two inner forms of the same quasi-split reductive group are equal [K5] [Ch].

For $\Phi \in C_c^\infty(H(\mathbb{A}_F))$ and $f \in C_c^\infty(G(\mathbb{A}_F))$ we define

\[
\Phi^1(x) := \int_{\mathbb{A} \setminus A_H^q \times A_H^q} \Phi(\mathfrak{z}^{-1}z_2x) \frac{dz_1dz_2}{du} \\
f^1(x) := \int_{\tilde{A} \setminus A_G^q \times A_G^q} f(\mathfrak{z}^{-1}\mathfrak{z}_\theta x) \frac{d\mathfrak{z}d\mathfrak{z}_\theta}{dt}.
\]

8.2. Elliptic kernels. Let $\Phi \in C_c^\infty(H(\mathbb{A}_F))$, $f \in C_c^\infty(G(\mathbb{A}_F))$ and consider the kernel functions

\[ K_\Phi(x, y) := \sum_{\gamma} \Phi^1(x^{-1}\gamma y) : 1H(\mathbb{A}_F) \times 1H(\mathbb{A}_F) \rightarrow \mathbb{C} \]
\[ K_f(x, y) := \sum_{\delta} f^1(x^{-1}\delta y) : 1G(\mathbb{A}_F) \times 1G(\mathbb{A}_F) \rightarrow \mathbb{C} \]

where the first sum is over relatively regular elliptic $\gamma \in H(F)$ and the second is over relatively $\tau$-regular elliptic $\delta \in G(F)$. Define the integrals

\[
RT_\epsilon(\Phi) := \iint_{(H^\epsilon(F) \setminus 2H^\epsilon(\mathbb{A}_F))^2} K_\Phi(h_1, h_2)dh_1dh_2 \\
TTRT_\epsilon(f) := \iint_{G^\epsilon(F) \setminus 2G^\epsilon(\mathbb{A}_F) \times G^\theta(F) \setminus 1G^\theta(\mathbb{A}_F)} K_f(g_1, g_2)dg_1dg_2.
\]
Here the \( dh_i \) are both induced by the measure on \( {}^2H^\sigma(\mathbb{A}_F) \) fixed above and \( dg_1, dg_2 \) are induced by the measures on \( {}^2G^\sigma(\mathbb{A}_F) \) and \( {}^2G^\sigma(\mathbb{A}_F) \) fixed above, respectively. These integrals are absolutely convergent (see the proof of \([H, \text{Theorem 4.1}]\)).

8.3. **Stable geometric expansions.** Using standard manipulations (compare \([H]\)), we rewrite

\[
RT_e(\Phi) = \sum_{\gamma_0} \sum_{\gamma \sim \gamma_0} a(\gamma) R\sigma(\Phi)
\]

\[
TRT_e(f) = \sum_{\delta_0} \sum_{\delta \sim \delta_0} a^\tau(\delta) T\sigma(\delta)
\]

where the exterior sums are over a set of representatives for the stable relatively regular elliptic classes (resp. stable relatively \( \tau \)-regular elliptic classes) and the interior sums are over a set of representatives for the relative classes (resp. relative \( \tau \)-classes) in the stable relative class of \( \gamma_0 \) (resp. stable relative \( \tau \)-class of \( \delta_0 \)). Here

\[
a(\gamma) : = \text{vol}(H_\gamma(F)\backslash {}^2H_\gamma(\mathbb{A}_F)) = \text{vol}(H_\gamma(F)\backslash {}^1H_\gamma(\mathbb{A}_F)) = \tau(H_\gamma)
\]

\[
a^\tau(\delta) : = \text{vol}(G_\delta(F)\backslash {}^2G_\delta(\mathbb{A}_F)) = \text{vol}(G_\delta(F)\backslash {}^1G_\delta(\mathbb{A}_F)) = \tau(G_\delta),
\]

where the volumes are taken with respect to the measures fixed in \( \S 8.1 \). Here, as in \( \S 8.1 \), we are using the fact that \( \gamma \) and \( \delta \) are relatively elliptic and relatively \( \tau \)-elliptic, respectively, to conclude that \( {}^2H_\gamma(\mathbb{A}_F) = {}^1H_\gamma(\mathbb{A}_F) \) and \( {}^2G_\delta(\mathbb{A}_F) = {}^1G_\delta(\mathbb{A}_F) \). Note that with the choice of Haar measure fixed in \( \S 8.1 \), the measures occurring in the summands corresponding to \( \gamma \) in the same stable relative class as a given \( \gamma_0 \) are compatible with respect to (3.2.3) above. Similarly, the measures occurring in the summands corresponding to \( \delta \) in the same stable relative \( \tau \)-class as a given \( \delta_0 \) are compatible with respect to (3.2.3). This follows from the well-known fact that the Tamagawa numbers of two inner forms of the same quasi-split reductive group are equal \([K5]\) \([Ch]\). With this in mind, we group stable classes in (8.3.1) and obtain

\[
RT_e(\Phi) = \sum_{\gamma_0} \tau(H_{\gamma_0}) S\sigma_{\gamma_0}(\Phi)
\]

\[
TRT_e(f) = \sum_{\delta_0} \tau(G_{\delta_0}) ST\sigma_{\delta_0}(f)
\]

where the first sum is over a set \( \{\gamma_0\} \) of representatives for the stable relative classes in \( H(F) \) that consist of relatively regular elliptic elements and the second sum is over a set \( \{\delta_0\} \) of representatives for the stable relative \( \tau \)-classes in \( G(F) \) that consist of relatively \( \tau \)-regular semisimple elements. The measures inherent in the definition of \( S\sigma_{\gamma_0}(\Phi) \) and \( ST\sigma_{\delta_0}(f) \) are specified as in \( \S 8.1 \).
Applying Proposition 7.2 we can rewrite (8.3.3) as
\[
RT_e(\Phi) = \sum_{\gamma_0} \tau(H^\sigma \times H^\sigma) \sum_{\kappa_H} RO_{\gamma_0}^H(\Phi)
\]
and
\[
TRT_e(f) = \sum_{\delta_0} \tau(G^\sigma \times G^\sigma) \sum_{\kappa} TRO_{\delta_0}^\kappa(f).
\]
Here the interior sum indexed by \(\gamma_0\) is over \(\kappa_H \in \mathcal{R}(H_{\gamma_0}, H^\sigma \times H^\sigma; F)\) and the interior sum indexed by \(\delta_0\) is over \(\kappa \in \mathcal{R}(G_{\delta_0}, G^\sigma \times G^\sigma; F)\) (compare Proposition 7.2).

8.4. The unitary case. We now specialize our notation to our primary case of interest. Thus assume that \(H^\sigma = U^\sigma\) is a unitary group with respect to a quadratic extension of fields \(M/F\) with \(M\) a CM field and \(F\) a totally real field. In other words, we assume that there is a simple algebra \(D\) over \(F\) with center \(M\) and an involution \(\dagger\) of \(D\) such that the fixed field of \(\dagger\) acting on \(M\) is \(F\) and such that if \(R\) is an \(F\)-algebra then
\[
U^\sigma(R) := \{ g \in (D \otimes_F R)^\times : gg^\dagger = 1 \}.
\]

We let \(E/F\) be a quadratic extension of fields with \(E\) totally real and assume moreover that we are in the biquadratic situation, thus \(U := \text{Res}_{E/F} U^\sigma\) and \(\sigma\) is the automorphism induced by the generator of \(\text{Gal}(E/F)\) which we will also denote by \(\sigma\). We let \(\tau\) be the generator of \(\text{Gal}(M/F)\) which we will also denote by \(\tau\). Then \(\tau\) defines an automorphism \(\tau: G \to G\) such that the subgroup of \(G\) fixed by \(\tau\) is \(U\). Finally, choose a (finite-dimensional) representation
\[
U^\sigma_{F_{\infty}} \to \text{Aut}_R(V)
\]
and let \(G^\sigma_{F_{\infty}} \to \text{Aut}_R(\text{Res}_{M_{\infty}/F_{\infty}} V)\) be the representation obtained by restriction of scalars. We have the following proposition:

Proposition 8.1. Suppose that \(\Phi \in C^\infty_c(U(A_F))\) and \(f \in C^\infty_c(G(A_F))\) are factorable and that \(\Phi_v\) matches \(f_v\) for all finite places \(v\) of \(F\). Consider the following assumptions:

1. One has
\[
f_{\infty} = f_1 \times f_2 \in C^\infty_c(G^\sigma(F_{\infty}) \times G^\sigma(F_{\infty})) = C^\infty_c(G(F_{\infty}))
\]
with \(f_1^{-\tau} \ast f_2 = f_{L, \text{Res}_{M_{\infty}/F_{\infty}} V, \tau}\).

2. One has
\[
\Phi_{\infty} = \Phi_1 \times \Phi_2 \in C^\infty_c(U^\sigma(F_{\infty}) \times U^\sigma(F_{\infty})) = C^\infty_c(U(F_{\infty}))
\]
with \(\Phi_1^{-1} \ast \Phi_2 = c_{\infty} f_{E P, V}\) for some \(c_{\infty} \in \mathbb{R}_{>0}\).

If the assumptions hold, then for an appropriate choice of \(c_{\infty} \in \mathbb{R}_{>0}\) one has
\[
RT_e(\Phi) = 2TRT_e(f).
\]
In the proposition, \( f_{L, \text{Res}_{M_\infty/F_\infty}, V, \tau} \) is the Lefschetz function attached to the representation \( \text{Res}_{M_\infty/F_\infty} V \) of \( G_{\infty}^\sigma \) and the involution \( \tau \) of \( G_{\infty}^\sigma \), (see [BLS, Proposition 8.4]). Moreover \( f_{EP, V} \) is the Euler-Poincaré function attached to \( V \); this is simply the Lefschetz function in the case that the associated automorphism is trivial.

**Proof.** The functions \( f_{L, \text{Res}_{M_\infty/F_\infty}, V, \tau} \) and \( f_{EP, V} \) are stable in the sense of [La1, Définition 3.8.2] (see [CL, Théorème A.1.1] and [La2, Théorème 7.1]). Thus, in view of Proposition 4.8 and assumptions (2) and (1), any \( \gamma_0 \) (resp. \( \delta_0 \)) contributing a nonzero summand to \( RT_{\epsilon}(\Phi) \) (resp. \( TRT_{\epsilon}(f) \)) is relatively regular elliptic (resp. relatively \( \tau \)-regular elliptic) at \( F_\infty \). Applying [La1, Proposition 1.9.6 and Lemme 1.9.7] we conclude that for these places the set \( \infty \) is \( (H, H_{\gamma_0}) \) (resp. \( (G, G_{\delta_0}) \))-essential for any \( \gamma_0 \) (resp. \( \delta_0 \)) contributing a nonzero summand. Using the fact that \( f_{L, \text{Res}_{M_\infty/F_\infty}, V, \tau} \) and \( f_{EP, V} \) are stable and Proposition 4.8 again, we conclude that the \( \kappa \)-orbital integrals for \( \kappa \neq 1 \) in (8.3.4) all vanish, and hence

\[
RT_{\epsilon}(\Phi) = \sum_{\gamma_0} \frac{\tau(U^{\sigma} \times U^{\sigma})}{d(U_{\gamma_0}, U^{\sigma} \times U^{\sigma})} \text{SRO}_{\gamma_0}(\Phi)
\]

\[
TRT_{\epsilon}(f) = \sum_{\delta_0} \frac{\tau(G^{\sigma} \times G^{\sigma})}{d(G_{\delta_0}, G^{\sigma} \times G^{\sigma})} \text{STRO}_{\delta_0}(f).
\]

By [La1, Corollaire A.1.2] for all \( v | \infty \) the functions \( f_v \) and \( c_v \Phi_v \) match for an appropriate constant \( c_v \in \mathbb{R}_{>0} \) (see also [La2, Théorème 7.1]). We henceforth assume that \( f_v \) and \( \Phi_v \) match for all \( v \).

Since every relatively regular semisimple \( \gamma_0 \) is a norm of a \( \delta_0 \) by Lemma 3.11 and every relatively \( \tau \)-regular elliptic semisimple \( \delta_0 \) that has local norms at infinity has a global norm by Proposition 3.10, to complete the proof it suffices to show that

\[
\tau(U^{\sigma} \times U^{\sigma}) = \frac{\text{dim}(H_{\infty}^{\text{ab}}(A_{\infty}/F, U^{\sigma} \times U^{\sigma}) \to H_{\infty}^{1}(A_{\infty}/F, U^{\sigma} \times U^{\sigma}))}{\text{dim}(\ker(\text{Res}_{\infty}/F, U^{\sigma} \times U^{\sigma}))} = 1
\]

\[
\text{STRO}_{\gamma_0}(\Phi) = \text{STRO}_{\delta_0}(f).
\]

Moreover

\[
\text{dim}(U_{\gamma_0}, U^{\sigma} \times U^{\sigma}) = \text{dim}(H_{\infty}^{0}(A_{\infty}/F, U^{\sigma} \times U^{\sigma}) \to H_{\infty}^{0}(A_{\infty}/F, U^{\sigma} \times U^{\sigma})) = 1
\]

and

\[
\text{dim}(G_{\delta_0}, G^{\sigma} \times G^{\sigma}) = \text{dim}(H_{\infty}^{0}(A_{\infty}/F, G^{\sigma} \times G^{\sigma}) \to H_{\infty}^{0}(A_{\infty}/F, G^{\sigma} \times G^{\sigma})) = 1
\]

by the fact that \( \gamma_0 \) and \( \delta_0 \) are relatively elliptic and relatively \( \tau \)-elliptic, respectively, and [La1, Corollaire 1.9.3]. By [La1, Corollaire 1.7.4], we have

\[
\tau(U^{\sigma} \times U^{\sigma}) = \frac{\text{dim}(H_{\infty}^{0}(A_{\infty}/F, U^{\sigma} \times U^{\sigma}))}{\text{dim}(\ker(\text{Res}_{\infty}/F, U^{\sigma} \times U^{\sigma}))} = \frac{4}{\text{dim}(\ker(\text{Res}_{\infty}/F, U^{\sigma} \times U^{\sigma}))}
\]

\[
\tau(G^{\sigma} \times G^{\sigma}) = \frac{\text{dim}(H_{\infty}^{0}(A_{\infty}/F, G^{\sigma} \times G^{\sigma}))}{\text{dim}(\ker(\text{Res}_{\infty}/F, G^{\sigma} \times G^{\sigma}))} = \frac{2}{\text{dim}(\ker(\text{Res}_{\infty}/F, G^{\sigma} \times G^{\sigma}))}
\]

Here we are using the fact that \( H_{\text{ab}}^{0}(A_{\infty}/F, GL_n) = 1 \) and \( H_{\text{ab}}^{1}(A_{\infty}/F, H) = 2 \) if \( H \) is a (nonsplit) unitary group (see [HL, Lemma 1.2.1(i)] for the latter statement).
Since $G^\sigma$ is an inner form of a general linear group, the Hasse principle is valid for it. On the other hand, $G^\theta$ and $U^\sigma$ are unitary groups, so the Hasse principle is valid for them as well [HL, Lemma 1.2.1(i)], so $\ker_{ab}^1(F, U^\sigma \times U^\sigma) = \ker_{ab}^1(F, G^\sigma \times G^\theta) = 1$. In view of (8.4.3) and (8.4.4), this completes the proof of the proposition. □

9. Relative trace formulae

9.1. A simple relative trace formula. For $f \in C_c^\infty(G(\mathbb{A}_F))$ and a cuspidal unitary automorphic representation $\Pi$ of $G(\mathbb{A}_F)$, Arthur has shown [Ar1, Lemma 4.5, Lemma 4.8] that there is a (unique) function $K_{\Pi(f^1)}(x, y) \in L^2_0(G(F) \backslash G(\mathbb{A}_F))$ that is smooth in $x$ and $y$ separately with $L^2$-expansion

\begin{equation}
K_{\Pi(f^1)}(x, y) = \sum_{\phi \in \mathcal{B}(\Pi)} \Pi(f^1) \phi(x) \overline{\phi(y)}.
\end{equation}

Here $\mathcal{B}(\Pi)$ is an orthonormal basis of the $\Pi$-isotypic subspace $V_{\Pi} \leq L^2_0(G(F) \backslash G(\mathbb{A}_F))$ with respect to the pairing

\begin{equation}
V_{\Pi} \times V_{\Pi} \rightarrow \mathbb{C}
\end{equation}

\begin{equation}
(\phi_1, \phi_2) \mapsto \int_{G(F) \backslash G(\mathbb{A}_F)} \phi_1(y) \overline{\phi_2(y)} dy,
\end{equation}

with $dy$ induced by the Tamagawa measure. We emphasize that this expansion (9.1.1), in general, is only convergent in the $L^2$ sense. Following [H], we define

\begin{equation}
TRT(\Pi(f^1)) = \int_{G^\sigma(F) \backslash G^\sigma(\mathbb{A}_F) \times G^\theta(F) \backslash G^\theta(\mathbb{A}_F)} K_{\Pi(f^1)}(x, y) dx dy.
\end{equation}

The integral is absolutely convergent by [AGR, §2, Proposition 1]. The following simple relative trace formula is proved in [H] via a modification of the argument used to prove the usual simple trace formula:

Theorem 9.1. Let $f = f_{v_1} \otimes f_{v_2} \otimes f_{v_1 v_2}^v \in C_c^\infty(G(\mathbb{A}_F))$ be a factorable function such that

- $f_{v_1}$ is $F$-supercuspidal.
- $f_{v_2}$ is supported on relatively $\tau$-regular elliptic elements of $G(F_{v_2})$.

Then

\begin{equation}
TRT_c(f) := \sum_{\delta} \tau(G_\delta) TRO_\delta(f) = \sum_{\Pi} TRT(\Pi(f^1))
\end{equation}

where the sum on the left is over a set of representatives for the relatively $\tau$-regular elliptic classes in $G(F)$ and the sum on the right is over a set of representatives for the equivalence classes of cuspidal automorphic representations $\Pi$ of $1 G(\mathbb{A}_F)$.
Here we say that \( f_v \) is \( F \)-supercuspidal if \( f_v \) has zero integral along the unipotent radical of any proper parabolic of \( G_{F_v} \) that is defined over \( F \); i.e. is the base change to \( F_v \) of a parabolic subgroup of \( G \). As usual, we allow \( \tau \) to be trivial in the theorem above. By convention, an automorphic representation of \( 1G(\mathbb{A}_F) \) is the restriction to \( 1G(\mathbb{A}_F) \) of an automorphic representation of \( G(\mathbb{A}_F) \), and we consider two such to be equivalent if they are equivalent as representations of \( 1G(\mathbb{A}_F) \).

Let \( K_\infty \leq G(F_\infty) \) be a maximal compact subgroup. We note that if \( \Pi \) is cuspidal and \( f \) is \( K_\infty \)-finite or \( \Pi(f_1) \) has finite rank then we have

\[
TRT(\Pi(f_1)) = \sum_{\phi \in \mathcal{B}(\Pi)} P_{G^\sigma}(\Pi(f_1)\phi)P_{G^\theta}(\phi)
\]

where the sum is over an orthonormal basis \( \mathcal{B}(\Pi) \) of the \( \Pi \)-isotypic subspace of \( L^2_0(G(F) \setminus 1G(\mathbb{A}_F)) \) consisting of smooth vectors (see (1.1.1) for the definition of \( P_{G^\sigma} \)). For any \( f \in C^\infty_c(G(\mathbb{A}_F)) \), if \( TRT(\Pi(f_1)) \) is nonzero then \( \Pi \) is both \( G^\sigma \) and \( G^\theta \)-distinguished.

9.2. Comparison. Upon combining Proposition 8.1 and Theorem 9.1, we obtain the following proposition:

**Proposition 9.2.** Suppose that \( \Phi = \otimes_v' \Phi_v \in C^\infty_c(U(\mathbb{A}_F)) \) and \( f = \otimes_v' f_v \in C^\infty_c(G(\mathbb{A}_F)) \) are factorable, and satisfy the following conditions:

- \( \Phi_v \) matches \( f_v \) for all \( v \).
- \( \Phi_\infty \) and \( f_\infty \) satisfy conditions (1-2) of Proposition 8.1.
- There is a finite place \( v_1 \) such that \( \Phi_{v_1} \) is \( F \)-supercuspidal.
- There is a place \( v_2 \) of \( F \) such that \( f_{v_2} \) is \( F \)-supercuspidal.
- There is a place \( v_3 \) of \( F \) such that \( \Phi_{v_3} \) is supported on relatively regular elliptic semisimple elements.
- There is a place \( v_4 \) of \( F \) such that \( f_{v_4} \) is supported on relatively \( \tau \)-regular elliptic semisimple elements.

Under the above assumptions, we have

\[
\sum_{\pi} RT(\pi(\Phi^1)) = 2 \sum_{\Pi} TRT(\Pi(f_1)),
\]

where the sums are over equivalence classes of cuspidal automorphic representations \( \pi \) of \( U(\mathbb{A}_F) \) and \( \Pi \) of \( 1G(\mathbb{A}_F) \), respectively. \( \square \)

Note that we do not require that the places \( v_i \) be distinct. Here \( RT(\pi(\Phi^1)) \) is defined to be \( TRT(\Pi(f_1)) \) in the \( \tau = 1 \) case.

10. Application

For this entire section we will place ourselves in the following special case of the construction exposed in the previous sections. Let \( E/F \) be a quadratic extension of totally real...
fields and let $M/F$ be a CM extension. Let $U^\sigma$ be a unitary group over $F$ as in (8.4.1) and $U := \text{Res}_{E/F} U^\sigma$. We let $\sigma$ be the automorphism of $U$ induced by the generator of $\text{Gal}(E/F)$, which we will also denote by $\sigma$. The groups $G^\sigma = \text{Res}_{M/F} U^\sigma$ and $G = \text{Res}_{M/F} U$ are isomorphic to inner forms of $\text{Res}_{M/F} \text{GL}_n$ and $\text{Res}_{M/E} \text{GL}_n$, respectively, for some $n$.

When we refer to the base change map below, we will mean the (partially defined) functorial lifting with respect to the map of $L$-groups

$$b : \mathcal{L} U \longrightarrow \mathcal{L} G$$

induced by the natural inclusion $U \to G$ (see [HL]).

**Definition 10.1.** Let $\pi$ be a cuspidal automorphic representation of $U^\sigma(\mathbb{A}_E) = U(\mathbb{A}_F)$. We say that a cuspidal automorphic representation $\Pi$ of $G^\sigma(\mathbb{A}_E) = G(\mathbb{A}_F)$ is a **weak base change** of $\pi$ if $\Pi_w$ is the base change of $\pi_w$ for all places $w$ of $E$ satisfying the following:

- $w$ is infinite,
- $ME/E$ is split at $w$, or
- $\pi_w$ and $U^\sigma_{Ew}$ are unramified.

By strong multiplicity one for $G$ [Ba], if a weak base change of $\pi$ exists then it is unique. Suppose that $\pi$ and $\pi'$ are cuspidal and both admit weak base changes to $G(\mathbb{A}_F)$. If $\pi$ and $\pi'$ are moreover **nearly equivalent**, i.e. $\pi_v \cong \pi'_v$ for almost all places $v$, then their weak base changes are obviously equal.

**10.1. Statement of theorem.** To state the main theorem of this section, it is convenient to introduce a definition. Let $K_{U_\infty} \leq U(F_\infty)$ be a maximal compact subgroup and let $V$ be a representation of $U(F_\infty)$. Let $u := \text{Lie}(U_{F_\infty}) \otimes_{\mathbb{R}} \mathbb{C}$ be the complexification of the real Lie group $U(F_\infty)$.

**Definition 10.2.** An automorphic representation $\pi$ of $U(\mathbb{A}_F)$ has **nonzero cohomology with coefficients in $V$** if $H^*(u, K_{U_\infty}; \pi_\infty \otimes V)$ is not identically zero.

We have the following theorem:

**Theorem 10.3.** Let $\pi$ be a cuspidal automorphic representation of $U^\sigma(\mathbb{A}_E) = U(\mathbb{A}_F)$ that admits a weak base change $\Pi$ to $G(\mathbb{A}_F)$. Suppose that $\pi$ satisfies the following conditions:

1. There is a finite-dimensional representation $V$ of $U_{F_\infty}$ such that $\pi$ has nonzero cohomology with coefficients in $V$.
2. There is a finite place $v_1$ of $F$ totally split in $ME/F$ such that $\pi_{v_1}$ is supercuspidal.
3. There is a finite place $v_2 \neq v_1$ of $F$ totally split in $ME/F$ such that $\pi_{v_2}$ is in the discrete series.
4. For all places $v$ of $F$ such that $ME/F$ is ramified and $M/F$, $E/F$ are both nonsplit at $v$ the weak base change $\Pi$ of $\pi$ to $G(F)$ has the property that $\Pi_v$ is relatively $\tau$-regular.
If the automorphic representation $\Pi$ is both $G^\sigma$ and $G^\theta$-distinguished then there is a cuspidal automorphic representation $\pi'$ of $U^\sigma(\mathbb{A}_E) = U(\mathbb{A}_F)$ that is $U^\sigma$-distinguished and nearly equivalent to $\pi$. Moreover, we can take $\pi'$ to have nonzero cohomology with coefficients in $V$.

Theorem 10.3 will be proven later in this section. Combining it with the work of Jacquet, Lapid and their collaborators, and Flicker and his collaborators, we obtain the following corollary:

**Corollary 10.4.** Assume that $U^\sigma$ is quasi-split or more generally that $G^\theta$ and $G^\sigma$ are quasi-split. Let $\pi$ be a cuspidal automorphic representation of $U(\mathbb{A}_F)$ satisfying conditions (1)-(4) of Theorem 10.3. The representation $\pi$ admits a weak base change $\Pi$ to $\text{GL}_n(\mathbb{A}_{ME})$. If the partial Asai $L$-function $L^S(s, \Pi; r)$ has a pole at $s = 1$ then some cuspidal automorphic representation $\pi'$ of $U(\mathbb{A}_F)$ nearly equivalent to $\pi$ is $U^\sigma$-distinguished. Moreover, we can take $\pi'$ to have nonzero cohomology with coefficients in $V$.

We require the following lemma for the proof of Corollary 10.4 and also below in the proof of Theorem 10.3:

**Lemma 10.5.** Suppose that $\Pi$ is a cuspidal automorphic representation of $G(\mathbb{A}_F)$. If $\Pi$ is $G^\theta$-distinguished, then $\Pi \cong \Pi^\theta$. If $\Pi$ is $G^\sigma$-distinguished, then $\Pi^\sigma \cong \Pi^\sigma$.

**Proof.** Both of these are well-known. For the first, see [J1, §3]. For the second, assume that $\Pi$ is $G^\sigma$-distinguished. For places $v$ of $F$ split in $E/F$, it is trivial to check that $\Pi^\sigma_v \cong \Pi^\sigma_v$ using an analogue of the proof of Proposition 10.6 given below. If $v$ is inert (and unramified) in $E/F$, the fact that $\Pi^\sigma_v \cong \Pi^\sigma_v$ is [P, Corollary 2] (see also [Fl2]). Thus $\Pi^\sigma \cong \Pi^\sigma$ by strong multiplicity one. □

We also require the following proposition in the proof of Theorem 10.3:

**Proposition 10.6.** Let $\Xi$ be the set of places of $F$ that split in $E/F$, let $\pi$ be a cuspidal automorphic representation of $U(\mathbb{A}_F)$. If $\pi$ is $U^\sigma$-distinguished, then $\pi^\sigma \equiv (\pi_\Xi)^\sigma$.

**Proof.** We may assume, without loss of generality, that the $\phi_0$ in the space of $\pi$ with nonzero period over $U^\sigma(\mathbb{A}_F)$ is factorable. Write $\phi_0 = \otimes_v \phi_{0,v}$, where the tensor product is over all places of $F$. For $v \in \Xi$, choose an isomorphism $U_{F_v} \cong U_{F_v}^\sigma \times U_{F_v}^\sigma$ intertwining $\sigma$ with $(x, y) \mapsto (y, x)$. Using this isomorphism, we can and do decompose

$$(10.1.1) \quad \pi_v \cong \pi_{1,v}^\sigma \otimes \pi_{2,v}^\sigma$$

for some admissible representations $\pi_{i,v}^\sigma$ of $U^\sigma(F_v)$. Thus

$$\pi_v^\sigma \cong \pi_{2,v}^\sigma \otimes \pi_{1,v}^\sigma.$$
For a fixed \( v \in \Xi \), let \( V_{\pi_1,v} \), \( V_{\pi_2,v} \), and \( V_{\pi} \) be the spaces of the representations \( \pi_1,v \), \( \pi_2,v \), and \( \pi \), respectively. Consider the bilinear pairing

\[
V_{\pi_1,v} \otimes V_{\pi_2,v} \hookrightarrow V_{\pi} \to \mathbb{C}.
\]

Here the first map is \((\phi_1, \phi_2) \mapsto (\otimes_{v' \neq v} \phi_{0,v'}) \otimes (\phi_1 \otimes \phi_2)\) and the second is \( \phi \mapsto \mathcal{P}_{U^\sigma}(\phi) \). This bilinear pairing is \( U^\sigma(F_v) \)-equivariant, and is nonzero by hypothesis. By the irreducibility of \( \pi_v \), we conclude that \( \pi_2,v \cong \pi_1,v \) and thus \( \pi_\sigma \cong \pi_v^\vee \).

\[\Box\]

We give the proof of Corollary 10.4 now:

10.2. **Proof of Corollary 10.4.** We assume the notation and hypotheses of Corollary 10.4. Let \( \Pi \) be the weak base change of \( \pi \); it exists by the proof of [HL, Theorem 3.1.4]. Since \( \Pi \) is a weak base change we have \( \Pi_v \cong \Pi_v^\tau \) for almost all places \( v \). By strong multiplicity one we conclude that \( \Pi \cong \Pi^\tau \). View \( \Pi \) as an automorphic representation of \( \text{Res}_{M/E/M} \text{GL}_n(A_M) \).

Let \( r : L\text{Res}_{M/E/M} \text{GL}_n \to \text{GL}_{n^2}(\mathbb{C}) \) be the Asai representation (see [R, §6] or [Fl1] for the definition of this representation). By assumption the partial Asai \( L \)-function

\[
L^S(s, \Pi; r)
\]

has a pole at \( s = 1 \). Here \( S \) is a finite set of places of \( M \) containing the infinite places and all finite places where \( ME/M \) or \( \Pi_v \) is ramified. We note that we are using the fact that \( L^S(s, \Pi; r) \) admits a meromorphic continuation to a closed right half-plane containing \( s = 1 \), a fact established by Flicker and Flicker-Zinoviev [Fl1] [FlZ, Theorem] using the Langlands-Shahidi method [Sh] and an adaptation of the Rankin-Selberg method of Jacquet, Piatetski-Shapiro, and Shalika [JPSS]. As a byproduct of this method, Flicker and Flicker-Zinoviev also establish in [FlZ, Theorem] that if \( L^S(s, \Pi; r) \) has a pole at \( s = 1 \), then \( \Pi \) is distinguished by \( \text{GL}_{n/M} \). This implies that \( \Pi_\sigma \cong \Pi_\tau^\vee \) by Lemma 10.5.

Writing \( L \) for the subfield of \( ME \) fixed by \( \theta := \sigma \circ \tau \), note that \( ME/L \) splits at all infinite places. Since \( \Pi_\sigma \cong \Pi_\tau^\vee \) and \( \Pi_\tau \cong \Pi \) we have \( \Pi_\theta^\vee \cong \Pi \). Thus, applying results of Jacquet ([J1, Theorem 3 and 4] and [J2]) we conclude that \( \Pi \) is distinguished by “the” quasi-split unitary group in \( n \)-variables with respect to \( ME/L \).

The corollary now follows from Theorem 10.3.

\[\Box\]

10.3. **Preparations for the proof of Theorem 10.3.** We isolate three steps in the proof of Theorem 10.3 in the following lemmas. If the reader so desires, (s)he can skip this subsection and refer back to it as needed during the following subsection.
For the purpose of stating a lemma we develop some notation. Assume that we are in the biquadratic case of §3.1 and let \( v \) be a place of \( F \) split in \( E/F \). Suppose \( \Pi_v \) is an irreducible admissible representation of \( G(F_v) \). Write
\[
\mathcal{H}_{\Pi_v} := \text{Im}(C^\infty_c(G(F_v)) \rightarrow \text{End}_C(V_{\Pi_v})),
\]
where the map sends \( f \) to \( \Pi_v(f) \). For any \( x, y \in G(F_v) \) we have linear left multiplication by \( x \) and right multiplication by \( y \) maps
\[
L_x, R_y : \text{End}_C(V_{\Pi_v}) \rightarrow \text{End}_C(V_{\Pi_v})
\]
given by \( L_x(T) := \Pi_v(x^{-1}) \circ T \) and \( R_y(T) := T \circ \Pi_v(y^{-1}) \).

**Lemma 10.7.** The space of linear forms \( \ell : \mathcal{H}_{\Pi_v} \rightarrow \mathbb{C} \) satisfying \( L_x(\ell) = R_y(\ell) = \ell \) for \( (x, y) \in G^\sigma \times G^\theta(F_v) \) is at most one-dimensional.

A linear form as in the lemma is known as a \((G^\sigma(F_v), G^\theta(F_v))\)-invariant linear form.

**Proof.** The natural isomorphism
\[
\text{End}_C(V_{\Pi_v})^\vee \cong V_{\Pi_v} \otimes V_{\Pi_v}^\vee,
\]
is \( G(F_v) \times G(F_v) \)-equivariant. A linear form \( \ell \) as in the lemma is sent to (10.3.1)
\[
(V_{\Pi_v})^{G^\sigma(F_v)} \otimes (V_{\Pi_v}^\vee)^{G^\theta(F_v)}
\]
under this isomorphism. Since \( \Pi_v \cong \Pi_1v \otimes \Pi_2v \) for some admissible representations \( \Pi_{iv} \) of \( G^\sigma(F_v) \), it follows that (10.3.1) is at most one dimensional. This proves that the space of linear forms satisfying the hypotheses of the lemma is at most one dimensional. \[ \square \]

We now record a lemma on supercuspidal forms. Let \( v \) be a finite place of \( F \) that splits completely in \( ME/F \). Thus we have isomorphisms

(10.3.2)
\[
\begin{align*}
U_{F_v} & \cong (U^\sigma)_{F_v}^2 \\
G_{F_v} & \cong U_{F_v}^2 \cong (U^\sigma)_{F_v}^4
\end{align*}
\]
intertwining \( \sigma \) with \( (x, y) \mapsto (y, x) \) (resp. \( (x, y, z, w) \mapsto (z, w, x, y) \)) and \( \tau \) with \( (x, y, z, w) \mapsto (y, x, w, z) \). Let \( \pi_v \) be a unitary admissible representation of \( U(F_v) \) satisfying \( \pi_v^\vee \cong \pi_v^\sigma \); thus we can and do decompose
\[
\pi_v \cong \pi_v' \otimes \pi_v''
\]
for some admissible representation \( \pi_v' \) of \( U^\sigma(F_v) \) using (10.3.2). Let \( \Pi_v \) be the base change of \( \pi_v \) to \( G(F_v) \). We can and do factor
\[
\Pi_v = \pi_v \otimes \pi_v^\vee \cong \pi_v' \otimes \pi_v'' \otimes \pi_v'' \otimes \pi_v'
\]
with respect to the second line of (10.3.2). We also write \( \Pi'_v = \pi_v' \otimes \pi_v'' \).
Let $H$ be a reductive $F$-group. As above, we say that a function $f \in C_c^\infty(H(F_v))$ is $F$-supercuspidal if the integral of $f$ along the $F_v$-points of the unipotent radical of any $F$-rational proper parabolic subgroup of $H$ vanishes.

**Lemma 10.8.** If $\pi'_v$ is supercuspidal, then there are matching functions

$$f = f_1 \times f_2 \in C_c^\infty(G^\sigma \times G^\sigma(F_v)) \cong C_c^\infty(G(F_v))$$

and $\Phi \in C_c^\infty(U(F_v))$, both $F$-supercuspidal, such that

$$\text{tr} \left( \Pi'_v(f_1^{-1} \ast f_2 \circ \tau) \right) \neq 0.$$

**Proof.** Let $\Phi_1$ be a truncated diagonal matrix coefficient of $\pi'_v$ [HL, §1.9]. We simply let

$$f_1 = \Phi_1^{-1} \times \text{ch}_{K'_Uv},$$

$$f_2 = \text{mes}(K'_Uv)^{-2} \times \text{ch}_{K'_Uv},$$

$$\Phi = \Phi_1^{-1} \times \text{ch}_{K'_Uv}$$

for a sufficiently small compact open subgroup $K'_Uv \leq U^\sigma(F_v)$ such that $\Phi_1 \in C_c^\infty(U^\sigma(F_v)//K'_Uv)$.

The functions $f_1 \times f_2$ and $\Phi$ match by Proposition 4.8. \qed

We require an analogous lemma in the discrete series case:

**Lemma 10.9.** If $\pi'_v$ is in the discrete series, then there are matching functions

$$f = f_1 \times f_2 \in C_c^\infty(G^\sigma \times G^\sigma(F_v)) \cong C_c^\infty(G(F_v))$$

and $\Phi \in C_c^\infty(U(F_v))$, supported on the relatively $\tau$-regular elliptic subset of $G(F_v)$ and the relatively regular elliptic subset of $U(F_v)$, respectively, such that

$$\text{tr} \left( \Pi'_v(f_1^{-1} \ast f_2 \circ \tau) \right) \neq 0.$$

**Proof.** Let $G^{re}(F_v) \subset G(F_v)$ (resp. $U^{re}(F_v) \subset U(F_v)$) denote the subset of relatively $\tau$-regular elliptic elements (resp. regular elliptic elements). By definition, $G^{re}(F_v)$ is the preimage of the set

$$\{(x, y, y^{-1}, x^{-1}) \in (U^\sigma)^4(F_v) : xy \text{ is elliptic regular} \} \subset S(F_v)$$

under the map $g \mapsto gg^{-\theta}$. Similarly, $U^{re}(F_v)$ is the preimage of the set

$$\{(x, x^{-1}) \in (U^\sigma)^2(F_v) : x \text{ is elliptic regular} \} \subset Q(F_v)$$

under the map $g \mapsto gg^{-\sigma}$. It follows that both $G^{re}(F_v) \subset G(F_v)$ and $U^{re}(F_v) \subset U(F_v)$ are open and intersect arbitrarily small neighborhoods of the identity.

Let $\Theta_{\pi'_v}$ be the character of $\pi'_v$. Using a well-known result of Harish-Chandra, we view $\Theta_{\pi'_v}$ as a locally constant function on the elliptic regular set of $U^\sigma(F_v)$ and as a locally integrable function on all of $U^\sigma(F_v)$. Since $\pi'_v$ is in the discrete series, there is a regular elliptic $\gamma_0 \in U^\sigma(F_v)$ such that $\Theta_{\pi'_v}(\gamma_0) \neq 0$ [Ro1, Proposition 5.5]. Note $(\gamma_0, 1, 1, 1) \in U^\sigma(F_v)^4 \cong G(F_v)$ is relatively $\tau$-elliptic regular. By the openness statement above, we can and do choose a
sufficiently small compact open subgroup $K'_{Uv} \leq U^\sigma(F_v)$ and a function $\Phi_1 \in C_c^\infty(U^\sigma(F_v))$ supported in the elliptic regular set of $U^\sigma(F_v)$ such that

$$f_1 \times f_2 = (\Phi_1^{-1} \times \text{ch}_{K'_{Uv}}) \times \text{ch}_{K'_{Uv}} \times \text{ch}_{K'_{Uv}}$$

is supported in $G^\sigma(F_v)$ and $\text{tr}(\pi'_1(\Phi_1)) \neq 0$. Here we are using the fact that $\Theta_{\pi'_1}$ is a locally constant function on the elliptic regular set of $U^\sigma(F_v)$. By Proposition 4.8 the functions $f_1 \times f_2$ and $\Phi := \Phi_1^{-1} \times \text{ch}_{K'_{Uv}}$ match, and hence $f_1 \times f_2$ and $\Phi := \Phi_1^{-1} \times \text{ch}_{K'_{Uv}}$ satisfy the requirements of the lemma. 

\[ \Phi = \Phi_1 \otimes \Phi_\infty \in C_c^\infty(U(A_F)) \]

\[ f = f_\infty \otimes f_\infty \in C_c^\infty(G(A_F)) \]

be factorable functions satisfying the hypotheses of Proposition 9.2. Such functions exist by Lemma 4.5, Proposition 4.8, Theorem 5.1, Lemma 10.8 and Lemma 10.9. Thus by Proposition 9.2 we have

\[ \sum_{\pi'} RT(\pi'(\Phi_1)) = 2 \sum_{\Pi'} T_{\Pi'}(f^1) \]  

Here the sum on the left is over equivalence classes of cuspidal automorphic representations of $1U(A_F) = U(A_F)$ and the sum on the right is over equivalence classes of cuspidal automorphic representations of $1G(A_F)$. Let $S$ be a finite set of places containing all infinite places and all places where $\pi$ is ramified. Choose compact open subgroups $K^S_{Uv} \leq U(A^S_F), K^S \leq G(A^S_F)$ such that $K^S_{Uv}$ and $K^S_v$ are hyperspecial for all $v \not\in S$ and $\pi^S$ (resp. $\Pi^S$) contains the

10.4. Proof of Theorem 10.3: Separating Hecke characters. In this subsection we use our trace formula identity Proposition 9.2 together with an adaptation of the argument of [JL, §3] (see also [Hak1, §13]) to reduce the proof of Theorem 10.3 to a nonvanishing statement that will be proved in the following subsection. We assume the hypotheses of Theorem 10.3.

By assumption, $\pi$ has nonzero cohomology with coefficients in $V$. In view of Proposition 10.6 this implies that there is a representation $V_1$ of $U^\sigma_{F_\infty}$ such that $V \cong V_1 \boxtimes V_1^\vee$. Let $K_\infty \leq G(F_\infty)$ (resp. $K^\infty_{U\infty} \leq U(F_\infty)$) be a maximal compact subgroup. We claim that we can choose $f_\infty \in G(F_\infty)$ and $\Phi_\infty \in C_c^\infty(U(F_\infty))$ such that, are right $K_\infty$ and right $K^\infty_{U\infty}$-finite, respectively, and satisfy the hypotheses (1-2) of Proposition 8.1 for the representations $V_1$. To see this we recall that Lefschetz functions are finite under the left and right action of the relevant maximal compact subgroup [BLS, Proposition 8.4]. Thus it follows from the Dixmier-Malliavin lemma [DM] that we can choose right-$K^\infty_{\infty} := K_\infty \cap G^\sigma(F_\infty)$-finite $f_1, f_2 \in C_c^\infty(G^\sigma(F_\infty))$ such that $f_1^{-1} \ast f_2 = f_L,_{\text{Res}_{M_{\infty}/F_\infty}V_1, \tau}$. A similar argument with $G(F_\infty)$ replaced by $U(F_\infty)$ together with Proposition 8.1 implies our claim. We henceforth assume $\Phi_\infty$ and $f_\infty$ satisfying the conclusion of our claim.

Now let

$$\Phi = \Phi_\infty \otimes \Phi_\infty \in C_c^\infty(U(A_F))$$

$$f = f_\infty \otimes f_\infty \in C_c^\infty(G(A_F))$$

be factorable functions satisfying the hypotheses of Proposition 9.2. Such functions exist by Lemma 4.5, Proposition 4.8, Theorem 5.1, Lemma 10.8 and Lemma 10.9. Thus by Proposition 9.2 we have

\[ \sum_{\pi'} RT(\pi'(\Phi_1)) = 2 \sum_{\Pi'} T_{\Pi'}(f^1) \]  

Here the sum on the left is over equivalence classes of cuspidal automorphic representations of $1U(A_F) = U(A_F)$ and the sum on the right is over equivalence classes of cuspidal automorphic representations of $1G(A_F)$. Let $S$ be a finite set of places containing all infinite places and all places where $\pi$ is ramified. Choose compact open subgroups $K^S_{Uv} \leq U(A^S_F), K^S \leq G(A^S_F)$ such that $K^S_{Uv}$ and $K^S_v$ are hyperspecial for all $v \not\in S$ and $\pi^S$ (resp. $\Pi^S$) contains the
unit representation of $K^S_v$ (resp. $K^S$). We assume that $f^S \in C^\infty_c(G(\mathbb{A}^S_F)//K^S)$ and $\Phi^S \in C^\infty_c(U(\mathbb{A}^S_F)//K^S)$; then (10.4.1) implies the following identity:

\[
\sum_{\pi'} \text{tr}(\pi'(\Phi^S))RT(\pi'(\Phi^S ch_{K^S})) = 2 \sum_{\Pi'} \text{tr}(\Pi'(f^S))TRT(\Pi'(f^S ch_{K^S}))
\]

(compare [JL, §3(2)]). The reason (10.4.1) simplifies to (10.4.2) is simply that if $\pi'_v$ (resp. $\Pi'_v$) is unramified then it contains a unique fixed vector under the hyperspecial subgroup $K_{Uv}$ (resp. $K_v$).

We have the following lemma:

**Lemma 10.10.** Any $\Pi'$ contributing a nonzero summand to the right of (10.4.2) has nonzero cohomology with coefficients in $\text{Res}_{M_{\infty}/F_{\infty}}V$. Any $\pi'$ contributing a nonzero summand to the left of (10.4.2) has nonzero cohomology with coefficients in $V$.

**Proof.** Choose an isomorphism $G(F_\infty) \cong G^\sigma(F_\infty) \times G^\sigma(F_\infty)$ equivariant with respect to $\tau$ and intertwining $\sigma$ with $(x,y) \mapsto (y,x)$. Write $\Pi'_{\infty} = \Pi_1 \otimes \Pi_2$ for some representations $\Pi_i$ of $G^\sigma(F_\infty)$ using this isomorphism. For a fixed $f^S_{\infty} \in C^\infty_c(G(F^S_\infty))$, consider the linear forms

\[
\ell_i : \mathcal{H}_{\Pi_{\infty}} \rightarrow \mathbb{C}
\]

\[
(\Pi_1(f_1), \Pi_2(f_2)) \mapsto \text{tr}(\Pi_1(f_1^{-\tau} \ast f_2 \circ \tau))
\]

\[
(\Pi_1(f_1), \Pi_2(f_2)) \mapsto \sum_{\phi \in B(\Pi_{\infty}) K^S} P_{G^\sigma}(\Pi_1 \times \Pi_2((f_1 \times f_2)^{-1})\Pi'(f^S_{\infty})\phi) \overline{P_{G^\sigma}(\phi)}.
\]

They are both $(G^\sigma(F_v), G^\sigma(F_\infty))$-invariant and hence equal up to a constant multiple (possibly zero) by Lemma 10.7. Thus the first assertion of the lemma follows from the defining property of Lefschetz functions [BLS, Proposition 8.4] and Lemma 10.5. The proof of the second assertion is similar; one uses Proposition 10.6 instead of Lemma 10.5. \qed

By the lemma, the collection of $\Pi'$ on the right of (10.4.2) is finite in a sense independent of $f^S \in C^\infty_c(G(\mathbb{A}^S_F)//K^S)$ for fixed $f^S$ by our assumption on $f^S$. Indeed, the sum can be thought of as being over automorphic representations contributing to the cohomology of a locally symmetric space depending only on $f^S$ with coefficients in a fixed local system depending only on $f^S$ by Lemma 10.10. Using the supply of matching $f^S$ and $\Phi^S$ provided by Corollary 4.6 and Corollary 4.9 we separate strings of Hecke eigenvalues “outside $S^\sigma$” in (10.4.2) to arrive at the following refined identity:

\[
\sum_{\sigma^S \neq S} \text{tr}(\pi'(\Phi^S))RT(\pi'(\Phi^S ch_{K^S})) = 2\text{tr}(\Pi(f^S))TRT(\Pi(f^S ch_{K^S})).
\]

Here we are using Lemma 10.5 and strong multiplicity one for $G(\mathbb{A}_F)$ to isolate the contribution of $\Pi$ on the right hand side. We are also using the fact that when $ME/F$, $U$, and $G$ are unramified at a finite place $v$ then the base change map from irreducible admissible unramified representations of $U(F_v)$ to irreducible admissible unramified representations of $G(F_v)$ is injective [M, Corollary 4.2].
Let $S(ME)$ be the set of finite places of $F$ such that $ME/F$ is ramified and both $E/F$ and $M/F$ are nonsplit. We let $S_0 = \infty \cup \{v_1, v_2\}$ and $S_0(ME) = S(ME) \cup S_0$. Enlarging $S$ if necessary, we assume that $S_0(ME) \subseteq S$. To complete the proof of the theorem, we show that the left side of (10.4.3) is nonzero for some $f \in C_c^\infty(G(A_F))$ satisfying the various conditions we have placed earlier. In view of Theorem 5.1, it suffices to show that upon enlarging $S$ if necessary we can choose $f_S^\infty$ so that

$$TRT(\Pi(f_S^1ch_{K^S})) \neq 0$$

where $f_{S(ME)}$ is supported on relatively $\tau$-regular semisimple elements admitting norms, $f_{v_1}$ is $F$-supercuspidal and matches an $F$-supercuspidal $\Phi_{v_1}$ and $f_{v_2}$ is supported on relatively $\tau$-regular elliptic semisimple elements and matches a function $\Phi_{v_2}$ supported on relatively regular elliptic semisimple elements. This is done in the following subsection.

10.5. Proof of Theorem 10.3: Nonvanishing. We assume all of the notation and conventions of the previous section and the hypotheses of Theorem 10.3. In particular, $\Pi$ is both $G^\sigma$ and $G^\theta$-distinguished. We prove the following proposition:

Proposition 10.11. With notation as in §10.4, upon possibly enlarging $S$ we can choose a function $f_S^\infty \in C_c^\infty(G(F_S^\infty))$ so that

$$TRT(\Pi(f_S^1ch_{K^S})) \neq 0$$

where $K^S \subseteq G(A_S^\infty)$ is a hyperspecial subgroup, $f_{S(ME)}$ is supported on relatively $\tau$-regular semisimple elements admitting norms, $f_{v_1}$ is $F$-supercuspidal and matches an $F$-supercuspidal $\Phi_{v_1}$, and $f_{v_2}$ is supported on relatively $\tau$-regular elliptic semisimple elements and matches a function $\Phi_{v_2} \in C_c^\infty(U(F_{v_2}))$ supported on relatively regular elliptic semisimple elements.

This proposition completes the proof of Theorem 10.3 as noted at the end of the previous subsection.

Proof. We claim that we can choose a pure tensor $\phi_0 \in V_\Pi$ such that the restriction of the two forms

$$P_{G^\sigma}(\cdot) : V_\Pi \rightarrow \mathbb{C} \quad \text{and} \quad P_{G^\theta}(\cdot) : V_\Pi \rightarrow \mathbb{C}$$

to $\phi_0^S \otimes V_{\Pi,S}$ are nonzero. Indeed, by assumption, there are vectors $\phi_1, \phi_2 \in V_\Pi$ such that $P_{G^\sigma}(\phi_1) \neq 0$ and $P_{G^\theta}(\phi_2) \neq 0$. If either $P_{G^\sigma}(\phi_2) \neq 0$ or $P_{G^\theta}(\phi_1) \neq 0$ then we are done, otherwise $P_{G^\sigma}(\phi_1 + \phi_2)P_{G^\theta}(\phi_1 + \phi_2) \neq 0$. Thus there is a vector $\phi_0 \in V_\Pi$ such that $P_{G^\sigma}(\phi_0)P_{G^\theta}(\phi_0) \neq 0$. We may assume that $\phi_0$ is a pure tensor, which implies the claim.

Enlarging $S$ if necessary, we choose a function $f_{S_0(ME)} \in C_c^\infty(G(F_{S_0(ME)}))$ such that $\Pi(f_{S_0(ME)}^S)$ is the orthogonal projection onto $\phi_0^S$. This is possible by the Jacobson density theorem and the matching statements Lemma 4.5 and Proposition 4.8.
With this choice, for an orthonormal basis $\mathcal{B}(\Pi)$ of the $\Pi$-isotypic subspace of $L^2_0(G(F) \backslash G(\mathbb{A}_F))$ we have

\begin{equation}
(10.5.1)
\sum_{\phi \in \mathcal{B}(\Pi)^{KS}} \mathcal{P}_{G^\sigma}(\Pi'(f^1)\phi)\overline{\mathcal{P}_{G^\sigma}(\phi)} = \text{tr}(\Pi(f^S)) \sum_{a_i} \mathcal{P}_{G^\sigma}(\overline{\phi_0^{S_0(ME)}} \otimes \Pi'(f^1_{S_0(ME)})a_i)\mathcal{P}_{G^\sigma}(\phi_0^{S_0(ME)} \otimes a_i)
\end{equation}

where the sum is over an orthonormal basis $\mathcal{B}(\Pi)$ of $V_{\Pi_{S_0(ME)}}$ with respect to the Hermitian pairing

\[(\ ,\ ) : V_{\Pi_{S_0(ME)}} \times V_{\Pi_{S_0(ME)}} \longrightarrow \mathbb{C}\]

given by

\[(\psi_1, \psi_2) \longmapsto \int_{G(F) \backslash G(\mathbb{A}_F)} \phi_0(g^{S_0(ME)}) \otimes \psi_1(g^{S_0(ME)})\overline{\phi_0(g^{S_0(ME)})} \otimes \psi_2(g^{S_0(ME)})dgdg,\]

where $dg$ is the Tamagawa measure. Note that only finitely many of the $a_i$ terms will have a nonzero contribution to (10.5.1).

For the moment let $f_{S_0}$ be chosen so that $\Pi_{S_0}(f_{S_0})$ is the projection to the space spanned by $\phi_{0S_0}$. Consider the linear functional

\begin{equation}
(10.5.2)
\Theta : C^\infty_c(G(F_s(ME))) \longrightarrow \mathbb{C}
\end{equation}

\[f_{S(ME)} \longmapsto \sum_{a_i} \mathcal{P}_{G^\sigma}(\phi_0^{S_0} \otimes \Pi(f^1_{S_0(ME)})a_i)\mathcal{P}_{G^\sigma}(\overline{\phi_0^{S_0}} \otimes a_i).\]

For each $v \in S(ME)$ this defines a spherical matrix coefficient of $\Pi_v$ in the sense of §6. It is nonzero because we can choose $f_{S(ME)}^v \in C^\infty_c(G(F_s(ME)))$ such that $\Pi(f_{S(ME)}^v)$ is the projection onto the space spanned by $\phi_{0S_0(ME)}$. By assumption, $\Pi_v$ is relatively $\tau$-regular for $v \in S(ME)$, so we can and do choose $f(S(ME)) \in C^\infty_c(G(F_s(ME)))$ that is supported in the set of $\tau$-regular semisimple elements in $G(F_s(ME))$ that admit norms and such that $\Theta(f_{S(ME)}^v) \neq 0$. This $f_{S(ME)}$ admits a matching function $\Phi_{S(ME)} \in C^\infty_c(H(F_s(ME)))$ by Theorem 5.1 above.

We are left with choosing $f_{S_0}$. Fix an isomorphism

\begin{equation}
(10.5.3)
G(F_{S_0}) \cong G^\sigma(F_{S_0}) \times G^\sigma(F_{S_0})
\end{equation}

intertwining $\sigma$ with $(x, y) \mapsto (y, x)$ and $\tau$ with $(x, y) \mapsto (x^\tau, y^\tau)$. By Lemma 10.5 we can and do factor

\[\Pi_{0S_0} \cong \Pi_{1S_0} \otimes \Pi_{1S_0}'\]

with respect to (10.5.3) for some irreducible admissible representation $\Pi_{1S_0}$ of $G^\sigma(F_{S_0})$. The map

\[\ell_1 : \mathcal{H}_{\Pi_{0S_0}} \longrightarrow \mathbb{C}
\]

\[\Pi_{1v}(f_1) \otimes \Pi_{1v}'(f_2) \longmapsto \prod_{v \in S_0} \text{tr} \left( \Pi_{1v}(f_{1v} \ast f_{2v}^{-\tau} \circ \tau) \right)\]

is $(G^\sigma(F_{S_0}), G^\sigma(F_{S_0}))$-invariant in the sense of §10.3, and clearly not identically zero.
Notice the linear functional \( \ell_2 : \mathcal{H}_{S_0} \rightarrow \mathbb{C} \)

\[
\Pi(f_{S_0}) \mapsto \sum_{a_i} \mathcal{P}_{G^\sigma}(\phi_0^{S_0} \otimes \Pi(f^1_{S_0(\varepsilon F)})a_i) \mathcal{P}_{G^\sigma}(\phi_0^{S_0} \otimes a_i)
\]

is also \((G^\sigma(F_{S_0}), G^\sigma(F_{S_0}))\)-invariant. By Lemma 10.7 we have that 

\[
\ell_2 = c \ell_1
\]

for some constant \( c \in \mathbb{C} \). By our choice of \( f_{S(ME)} \) above the linear functional \( \ell_2 \) is not identically zero and hence we have that \( c \neq 0 \).

Choosing a factorable function

\[
f_{S_0}^\infty = f_1 \times f_2 \in C_c^\infty(G^\sigma \times G^\sigma(F_{S_0}^\infty)),
\]

we have

\[
(10.5.4) \quad \ell_2(f_{S_0}) = c \left( \text{tr}(\Pi_{1,\infty}(f_{L, \text{Res}_{\infty, F_{\infty}}V_1, \tau} \circ \tau)) \right) \left( \prod_{v \in S_0 \setminus \infty} \text{tr} \left( \Pi_{1,v}(f_{1,v} \ast f_{2,v}^{-\tau} \circ \tau) \right) \right)
\]

with \( V_1 \) as in §10.4. We now show that we can choose a test function \( f = f_1 \times f_2 \) satisfying the conditions at \( \infty, v_1, \) and \( v_2 \) stipulated in the statement of the proposition such that \((10.5.4)\) is nonzero; this will complete the proof of the proposition.

We work place by place. The factor corresponding to the infinite places is nonzero by [La2, Lemme 4.2]. Lemma 10.8 takes care of \( v = v_1 \), and Lemma 10.9 takes care of \( v = v_2 \).

\[ \square \]

**Acknowledgments**

The first named author appreciates the time Erez Lapid spent pointing out serious mistakes in an earlier version of this work and for thoughtful comments as the new version emerged. He would like to thank Chris Skinner for support throughout this project, and Hervé Jacquet, David Whitehouse, and Sophie Morel for useful conversations. He also thanks Heekyoung Hahn for help with editing. The second author thanks Dinakar Ramakrishnan, Elena Mantovan, Kimball Martin and David Whitehouse for helpful conversations and advice. Both authors thank the referees for thorough readings of the paper and their suggestions and corrections, some of which were incorporated.
